FOREWORD

This book gives you fully worked solutions for every question (discussions, investigations and projects excepted) in each chapter of our textbook *Mathematics HL (Core) third edition* which is one of the textbooks in our series **Mathematics for the International Student** intended for use with IB Diploma and Middle Years courses.

Correct answers can sometimes be obtained by different methods. In this book, where applicable, each worked solution is modelled on the worked example in the textbook.

Be aware of the limitations of calculators and computer modelling packages. Understand that when your calculator gives an answer that is different from the answer you find in the book, you have not necessarily made a mistake, but the book may not be wrong either.

We have a list of errata for our books on our website. Please contact us if you notice any errors in this book.

Since $\Delta > 0$ and Δ is a square, there are two distinct rational solutions.

$$\begin{aligned}

 \therefore & \Delta = b^2 - 4ac \\
 & = 4^2 - 4(5)(-3) \\

 \end{aligned}$$

Since $\Delta > 0$, there are two distinct real solutions.

$$\begin{aligned}

EXERCISE 1C

1 a For $3x^2 - 2x + 7 = 0$:

$$\text{sum of roots} = -\frac{b}{a} = -\frac{(-2)}{3} = \frac{2}{3}$$

$$\text{product of roots} = \frac{c}{a} = \frac{7}{3}$$

c For $5x^2 - 6x - 14 = 0$:

$$\text{sum of roots} = -\frac{b}{a} = -\frac{(-6)}{5} = \frac{6}{5}$$

$$\text{product of roots} = \frac{c}{a} = -\frac{14}{5}$$

2 For $kx^2 - (1+k)x + (3k+2) = 0$, $a = k$, $b = -(1+k)$, $c = 3k+2$

$$\therefore \text{sum of roots} = -\frac{b}{a} = -\frac{-(1+k)}{k} = \frac{k+1}{k}, \quad \text{product of roots} = \frac{c}{a} = \frac{3k+2}{k}$$

Now, sum of the roots is twice their product

$$\therefore \frac{k+1}{k} = 2 \left(\frac{3k+2}{k} \right)$$

$$\therefore k+1 = 2(3k+2)$$

$$\therefore k+1 = 6k+4$$

$$\therefore -3 = 5k$$

$$\therefore k = -\frac{3}{5}$$

b For $x^2 + 11x - 13 = 0$:

$$\text{sum of roots} = -\frac{b}{a} = -\frac{11}{1} = -11$$

$$\text{product of roots} = \frac{c}{a} = \frac{-13}{1} = -13$$

Substituting $k = -\frac{3}{5}$ into the equation gives

$$-\frac{3}{5}x^2 - (1 - \frac{3}{5})x + (-\frac{9}{5} + 2) = 0$$

$$\therefore -\frac{3}{5}x^2 - \frac{2}{5}x + \frac{1}{5} = 0$$

$$\therefore -\frac{1}{5}(3x^2 + 2x - 1) = 0$$

$$\therefore -\frac{1}{5}(3x-1)(x+1) = 0$$

$$\therefore x = \frac{1}{3} \text{ or } -1$$

$\therefore$ the roots of the equation are $\frac{1}{3}$ and -1

3 For $ax^2 - 6x + a - 2 = 0$, “a” = a, $b = -6$, $c = a - 2$

a sum of roots = $-\frac{b}{a}$

$$\therefore \alpha + 2\alpha = -\frac{(-6)}{a}$$

$$\therefore 3\alpha = \frac{6}{a} \quad \{\text{or } \alpha = \frac{2}{a} \quad \dots (1)\}$$

product of roots = $\frac{c}{a}$

$$\therefore \alpha \times 2\alpha = \frac{a-2}{a}$$

$$\therefore 2\alpha^2 = \frac{a-2}{a} \quad \dots (2)$$

b Substituting (1) into (2) gives

$$2 \left(\frac{2}{a} \right)^2 = \frac{a-2}{a}$$

$$\therefore 2 \left(\frac{4}{a^2} \right) = \frac{a-2}{a}$$

$$\therefore \frac{8}{a} = a - 2$$

$$\therefore 8 = a^2 - 2a$$

$$\therefore a^2 - 2a - 8 = 0$$

$$\therefore (a-4)(a+2) = 0$$

$$\therefore a = 4 \text{ or } -2$$

$$\begin{array}{ll} \text{If } a = 4, \text{ then } \alpha = \frac{2}{4} \quad \{\text{using (1)}\} & \text{If } a = -2, \text{ then } \alpha = \frac{2}{-2} \quad \{\text{using (1)}\} \\ & = -1 \\ & \text{and } 2\alpha = -2 \\ & = \frac{1}{2} \\ & \text{and } 2\alpha = 1 \\ \therefore a = 4 \text{ and the roots are } \frac{1}{2} \text{ and } 1 & \text{or } a = -2 \text{ and the roots are } -1 \text{ and } -2. \end{array}$$

- 4 For $kx^2 + (k - 8)x + (1 - k) = 0$, $a = k$, $b = k - 8$, $c = 1 - k$
Let the roots of the equation be m and $m + 2$.

$$\begin{array}{ll} \text{sum of roots} = -\frac{b}{a} & \text{Substituting (1) into (2) gives} \\ \therefore m + (m + 2) = -\frac{k - 8}{k} & \left(\frac{8 - 3k}{2k}\right) \left(\frac{8 - 3k}{2k} + 2\right) = \frac{1 - k}{k} \\ \therefore 2m + 2 = \frac{8 - k}{k} & \therefore \left(\frac{8 - 3k}{2k}\right) \left(\frac{8 + k}{2k}\right) = \frac{1 - k}{k} \\ \therefore 2m = \frac{8 - k}{k} & \therefore \frac{64 - 16k - 3k^2}{4k^2} = \frac{1 - k}{k} \\ \therefore m = \frac{8 - 3k}{2k} \quad \dots (1) & \therefore \frac{64 - 16k - 3k^2}{4k} = 1 - k \\ \text{and product of roots} = \frac{c}{a} & \therefore 64 - 16k - 3k^2 = 4k - 4k^2 \\ \therefore m(m + 2) = \frac{1 - k}{k} \quad \dots (2) & \therefore k^2 - 20k + 64 = 0 \\ & \therefore (k - 4)(k - 16) = 0 \\ & \therefore k = 4 \text{ or } 16 \end{array}$$

Using (1), if $k = 4$ then $m = \frac{8 - 3(4)}{2(4)} = \frac{-4}{8} = -\frac{1}{2}$, and $m + 2 = \frac{3}{2}$

and if $k = 16$ then $m = \frac{8 - 3(16)}{2(16)} = \frac{-40}{32} = -\frac{5}{4}$, and $m + 2 = \frac{3}{4}$

$\therefore k = 4$ and the roots are $-\frac{1}{2}$ and $\frac{3}{2}$ or $k = 16$ and the roots are $-\frac{5}{4}$ and $\frac{3}{4}$.

- 5 The roots of $x^2 - 6x + 7 = 0$ are α and β .

$$\begin{array}{ll} \text{sum of roots} = -\frac{-6}{1} & \text{and product of roots} = \frac{7}{1} \\ \therefore \alpha + \beta = 6 & \therefore \alpha\beta = 7 \end{array}$$

Now consider a quadratic equation with roots $\alpha + \frac{1}{\beta}$ and $\beta + \frac{1}{\alpha}$

$$\begin{array}{ll} \text{sum of roots} = \alpha + \frac{1}{\beta} + \beta + \frac{1}{\alpha} & \text{product of roots} = \left(\alpha + \frac{1}{\beta}\right) \left(\beta + \frac{1}{\alpha}\right) \\ = (\alpha + \beta) + \left(\frac{1}{\alpha} + \frac{1}{\beta}\right) & = \alpha\beta + 1 + 1 + \frac{1}{\alpha\beta} \\ = (\alpha + \beta) + \frac{\alpha + \beta}{\alpha\beta} & = 7 + 2 + \frac{1}{7} \\ = 6 + \frac{6}{7} & = 9 + \frac{1}{7} \\ = \frac{48}{7} & = \frac{64}{7} \end{array}$$

$\therefore$ a quadratic equation $ax^2 + bx + c = 0$ with roots $\alpha + \frac{1}{\beta}$ and $\beta + \frac{1}{\alpha}$ has $-\frac{b}{a} = \frac{48}{7}$ and $\frac{c}{a} = \frac{64}{7}$.

The simplest solution to this is $a = 7$, $b = -48$, $c = 64$.

$\therefore$ the simplest quadratic equation with roots $\alpha + \frac{1}{\beta}$ and $\beta + \frac{1}{\alpha}$ is $7x^2 - 48x + 64 = 0$.

- 6 The roots of $2x^2 - 3x - 5 = 0$ are p and q .

$$\therefore \text{sum of roots} = -\frac{-3}{2} \quad \text{and} \quad \text{product of roots} = \frac{-5}{2}$$

$$\therefore p + q = \frac{3}{2} \qquad \qquad \qquad \therefore pq = -\frac{5}{2}$$

Now consider a quadratic equation with roots $p^2 + q$ and $q^2 + p$.

$$\begin{aligned} \text{sum of roots} &= p^2 + q + q^2 + p & \text{product of roots} &= (p^2 + q)(q^2 + p) \\ &= (p^2 + q^2) + (p + q) & &= p^2q^2 + p^3 + q^3 + qp \\ &= [(p + q)^2 - 2pq] + (p + q) & &= (pq)^2 + [(p + q)^3 - 3p^2q - 3pq^2] + pq \\ &= \left(\frac{3}{2}\right)^2 - 2\left(-\frac{5}{2}\right) + \frac{3}{2} & &= (pq)^2 + [(p + q)^3 - 3pq(p + q)] + pq \\ &= \frac{9}{4} + 5 + \frac{3}{2} & &= \left(-\frac{5}{2}\right)^2 + \left(\frac{3}{2}\right)^3 - 3\left(-\frac{5}{2}\right)\left(\frac{3}{2}\right) + \left(-\frac{5}{2}\right) \\ &= \frac{35}{4} & &= \frac{25}{4} + \frac{27}{8} + \frac{45}{4} - \frac{5}{2} \\ & & &= \frac{147}{8} \end{aligned}$$

$\therefore$ a quadratic equation $ax^2 + bx + c = 0$ with roots $p^2 + q$ and $q^2 + p$

$$\text{has } -\frac{b}{a} = \frac{35}{4} \quad \text{and} \quad \frac{c}{a} = \frac{147}{8}.$$

$$\therefore b = -\frac{35}{4}a \quad \text{and} \quad c = \frac{147}{8}a$$

$$\therefore \text{the quadratic equation is } ax^2 - \frac{35}{4}ax + \frac{147}{8}a = 0, \quad a \neq 0$$

$$\therefore a\left(x^2 - \frac{35}{4}x + \frac{147}{8}\right) = 0, \quad a \neq 0$$

$$\therefore a(8x^2 - 70x + 147) = 0, \quad a \neq 0$$

- 7 $kx^2 + (k + 2)x - 3 = 0$ will have roots which are real and positive if:

- (1) $\Delta \geq 0$ (2) sum of roots > 0 (3) product of roots > 0

(1) $\Delta \geq 0$

$$\therefore (k + 2)^2 - 4(k)(-3) \geq 0$$

$$\therefore k^2 + 4k + 4 + 12k \geq 0$$

$$\therefore k^2 + 16k + 4 \geq 0$$

Now $k^2 + 16k + 4 = 0$ when

$$k = \frac{-16 \pm \sqrt{16^2 - 4(1)(4)}}{2(1)}$$

$$= \frac{-16 \pm \sqrt{240}}{2}$$

$$= \frac{-16 \pm 2\sqrt{60}}{2}$$

$$= -8 \pm \sqrt{60}$$

$\therefore k^2 + 16k + 4$ has sign diagram

$\therefore \Delta \geq 0$ when

$$k \leq -8 - \sqrt{60} \quad \text{or} \quad k \geq -8 + \sqrt{60}$$

(2) sum of roots > 0

$$\therefore -\frac{k + 2}{k} > 0$$

$-\frac{k + 2}{k}$ has sign diagram

$\therefore$ sum of roots > 0 when $-2 < k < 0$

(3) product of roots > 0

$$\therefore \frac{-3}{k} > 0$$

$-\frac{3}{k}$ has sign diagram

$\therefore$ product of roots > 0 when $k < 0$

$\therefore$ the only values of k which satisfy all three conditions are $-8 + \sqrt{60} \leq k < 0$.

But when $x = 2$, $y = 5$

$$\therefore 5 = a(2 - 5)(2 + 3)$$

$$\therefore 5 = a(-3)(5)$$

$$\therefore -15a = 5$$

$$\therefore a = -\frac{5}{15} = -\frac{1}{3}$$

$\therefore$ the equation is $y = -\frac{1}{3}(x - 5)(x + 3)$

$$\therefore y = -\frac{1}{3}(x^2 - 2x - 15)$$

$$\therefore y = -\frac{1}{3}x^2 + \frac{2}{3}x + 5$$

- 4 a** The vertex is $(2, 4)$,
so the quadratic has equation
 $y = a(x - 2)^2 + 4$ for some $a \neq 0$.
But the graph passes through the origin
 $\therefore 0 = a(0 - 2)^2 + 4$
 $\therefore 4a + 4 = 0$
 $\therefore a = -1$
 $\therefore$ the equation is $y = -(x - 2)^2 + 4$
- c** The vertex is $(3, 8)$,
so the quadratic has equation
 $y = a(x - 3)^2 + 8$ for some $a \neq 0$.
But the graph passes through $(1, 0)$
 $\therefore 0 = a(1 - 3)^2 + 8$
 $\therefore 0 = 4a + 8$
 $\therefore a = -2$
 $\therefore$ the equation is $y = -2(x - 3)^2 + 8$
- e** The vertex is $(2, 3)$,
so the quadratic has equation
 $y = a(x - 2)^2 + 3$ for some $a \neq 0$.
But the graph passes through $(3, 1)$
 $\therefore 1 = a(3 - 2)^2 + 3$
 $\therefore 1 = a + 3$
 $\therefore a = -2$
 $\therefore$ the equation is $y = -2(x - 2)^2 + 3$
- b** The vertex is $(2, -1)$,
so the quadratic has equation
 $y = a(x - 2)^2 - 1$ for some $a \neq 0$.
But the graph passes through $(0, 7)$
 $\therefore 7 = a(0 - 2)^2 - 1$
 $\therefore 7 = 4a - 1$
 $\therefore a = 2$
 $\therefore$ the equation is $y = 2(x - 2)^2 - 1$
- d** The vertex is $(4, -6)$,
so the quadratic has equation
 $y = a(x - 4)^2 - 6$ for some $a \neq 0$.
But the graph passes through $(7, 0)$
 $\therefore 0 = a(7 - 4)^2 - 6$
 $\therefore 9a - 6 = 0$
 $\therefore a = \frac{2}{3}$
 $\therefore$ the equation is $y = \frac{2}{3}(x - 4)^2 - 6$
- f** The vertex is $(\frac{1}{2}, -\frac{3}{2})$,
so the quadratic has equation
 $y = a(x - \frac{1}{2})^2 - \frac{3}{2}$ for some $a \neq 0$.
But the graph passes through $(\frac{3}{2}, \frac{1}{2})$
 $\therefore \frac{1}{2} = a(\frac{3}{2} - \frac{1}{2})^2 - \frac{3}{2}$
 $\therefore \frac{1}{2} = a - \frac{3}{2}$
 $\therefore a = 2$
 $\therefore$ the equation is $y = 2(x - \frac{1}{2})^2 - \frac{3}{2}$

EXERCISE 1F

- 1 a** $y = x^2 - 2x + 8$ meets $y = x + 6$
when $x^2 - 2x + 8 = x + 6$
 $\therefore x^2 - 3x + 2 = 0$
 $\therefore (x - 1)(x - 2) = 0$
 $\therefore x = 1$ or 2
Substituting into $y = x + 6$,
when $x = 1$, $y = 7$
and when $x = 2$, $y = 8$
 $\therefore$ the graphs intersect at $(1, 7)$ and $(2, 8)$.
- c** $y = x^2 - 4x + 3$ meets $y = 2x - 6$
when $x^2 - 4x + 3 = 2x - 6$
 $\therefore x^2 - 6x + 9 = 0$
 $\therefore (x - 3)^2 = 0$
 $\therefore x = 3$
Substituting into $y = 2x - 6$,
when $x = 3$, $y = 0$
 $\therefore$ the graphs touch at $(3, 0)$.
- b** $y = -x^2 + 3x + 9$ meets $y = 2x - 3$
when $-x^2 + 3x + 9 = 2x - 3$
 $\therefore x^2 - x - 12 = 0$
 $\therefore (x - 4)(x + 3) = 0$
 $\therefore x = 4$ or -3
Substituting into $y = 2x - 3$,
when $x = -3$, $y = 2(-3) - 3 = -9$
and when $x = 4$, $y = 2(4) - 3 = 5$
 $\therefore$ the graphs intersect at $(-3, -9)$ and $(4, 5)$.
- d** $y = -x^2 + 4x - 7$ meets $y = 5x - 4$
when $-x^2 + 4x - 7 = 5x - 4$
 $\therefore x^2 + x + 3 = 0$
which has $a = 1$, $b = 1$, $c = 3$
 $\therefore x = \frac{-1 \pm \sqrt{1^2 - 4(1)(3)}}{2(1)}$
 $\therefore x = \frac{-1 \pm \sqrt{-11}}{2}$
 $\therefore$ there are no real solutions
 $\therefore$ the graphs do not intersect.

2 a i

$\therefore y = x^2$ meets $y = x + 2$
at the points $(-1, 1)$ and $(2, 4)$.

ii Using the graph in **a i**, $x^2 > x + 2$
when $x < -1$ or $x > 2$.

b i

$\therefore y = x^2 + 2x - 3$ meets $y = x - 1$
at the points $(-2, -3)$ and $(1, 0)$.

ii Using the graph in **b i**,
 $x^2 + 2x - 3 > x - 1$ when
 $x < -2$ or $x > 1$.

c i

$\therefore y = 2x^2 - x + 3$ touches
 $y = 2 + x + x^2$ at the point $(1, 4)$.

ii Using the graph in **c i**,
 $2x^2 - x + 3 > 2 + x + x^2$
when $x \neq 1$.

d i

$\therefore y = \frac{4}{x}$ meets $y = x + 3$ at the
points $(-4, -1)$ and $(1, 4)$.

ii Using the graph in **d i**, $\frac{4}{x} > x + 3$
when $x < -4$ or $0 < x < 1$.

3 $y = 3x + c$ is a tangent to $y = x^2 - 5x + 7$ if they meet at exactly one point (touch).

$y = x^2 - 5x + 7$ meets $y = 3x + c$ when $x^2 - 5x + 7 = 3x + c$

$$\therefore x^2 - 8x + 7 - c = 0$$

The graphs meet exactly once when this equation has a repeated root $\therefore \Delta = 0$

$$\therefore (-8)^2 - 4(1)(7 - c) = 0$$

$$\therefore 64 - 28 + 4c = 0$$

$$\therefore 4c = -36$$

$$\therefore c = -9$$

4 $y = mx - 2$ is a tangent to $y = x^2 - 4x + 2$ if they meet at exactly one point (touch).

$y = x^2 - 4x + 2$ meets $y = mx - 2$ when $x^2 - 4x + 2 = mx - 2$

$$\therefore x^2 - (m + 4)x + 4 = 0$$

The graphs meet exactly once when this equation has a repeated root $\therefore \Delta = 0$

$$\therefore (-(m + 4))^2 - 4(1)(4) = 0$$

$$\therefore m^2 + 8m + 16 - 16 = 0$$

$$\therefore m(m + 8) = 0$$

$$\therefore m = 0 \text{ or } -8$$

5 Lines with y -intercept 1 have the form $y = mx + 1$.

$y = mx + 1$ is a tangent to $y = 3x^2 + 5x + 4$ if they meet at exactly one point (touch).

$y = 3x^2 + 5x + 4$ meets $y = mx + 1$ when $3x^2 + 5x + 4 = mx + 1$

$$\therefore 3x^2 + (5 - m)x + 3 = 0$$

The graphs meet exactly once when this equation has a repeated root $\therefore \Delta = 0$

$$\therefore (5 - m)^2 - 4(3)(3) = 0$$

$$\therefore 25 - 10m + m^2 - 36 = 0$$

$$\therefore m^2 - 10m - 11 = 0$$

$$\therefore (m + 1)(m - 11) = 0$$

$$\therefore m = -1 \text{ or } 11$$

$\therefore$ the required lines have gradient -1 or 11 .

6 a $y = x + c$ meets $y = 2x^2 - 3x - 7$

when $2x^2 - 3x - 7 = x + c$

$$\therefore 2x^2 - 4x - 7 - c = 0$$

The graphs will never meet if this equation

has no real roots $\therefore \Delta < 0$

$$\therefore (-4)^2 - 4(2)(-7 - c) < 0$$

$$\therefore 16 + 56 + 8c < 0$$

$$\therefore 8c < -72$$

$$\therefore c < -9$$

b Choose c such that $c < -9$,
for example $c = -10$:

EXERCISE 1G

1 Let the smaller of the integers be x .

The other integer is $(x + 12)$.

$\therefore$ the sum of their squares is

$$x^2 + (x + 12)^2 = 74$$

$$\therefore x^2 + x^2 + 24x + 144 = 74$$

$$\therefore 2x^2 + 24x + 70 = 0$$

$$\therefore x^2 + 12x + 35 = 0$$

$$\therefore (x + 7)(x + 5) = 0$$

$$\therefore x = -7 \text{ or } -5$$

So, the integers are -7 and 5 , or -5 and 7 .

3 Let the number be x so its square is x^2 .

$\therefore$ the sum is $x + x^2 = 210$

$$\therefore x^2 + x - 210 = 0$$

$$\therefore (x + 15)(x - 14) = 0$$

$$\therefore x = -15 \text{ or } 14$$

But x is a natural number, so $x > 0$,

$\therefore$ the number is 14 .

2 Let the number be x , so its reciprocal is $\frac{1}{x}$.

They have sum $x + \frac{1}{x} = 5\frac{1}{5}$

$$\therefore x^2 + 1 = \frac{26}{5}x$$

$$\therefore x^2 - \frac{26}{5}x + 1 = 0$$

$$\therefore 5x^2 - 26x + 5 = 0$$

$$\therefore (5x - 1)(x - 5) = 0$$

$$\therefore x = \frac{1}{5} \text{ or } 5$$

So, the number is either $\frac{1}{5}$ or 5 .

4 Suppose the numbers are x and $(x + 2)$.

Then $x(x + 2) = 255$

$$\therefore x^2 + 2x - 255 = 0$$

$$\therefore (x + 17)(x - 15) = 0$$

$$\therefore x = -17 \text{ or } 15$$

$\therefore$ the numbers are -17 and -15 ,
or 15 and 17 .

5 If the width of the rectangle is w cm, then its length is $(w + 4)$ cm.

$\therefore$ the area is $w(w + 4) = 26$

$$\therefore w^2 + 4w - 26 = 0$$

which has $a = 1$, $b = 4$, $c = -26$

$$\therefore w = \frac{-4 \pm \sqrt{4^2 - 4(1)(-26)}}{2(1)}$$

$$\therefore w = \frac{-4 \pm \sqrt{120}}{2} = -2 \pm \sqrt{30}$$

But $w > 0$, so $w = -2 + \sqrt{30}$

$$\approx 3.477$$

So, the width is approximately 3.48 cm.

- 6 a** The base has sides of length x cm, so the areas of the top and bottom surfaces are both x^2 cm².

The box has height $(x + 1)$ cm, so the area of each of the side faces is $x(x + 1)$ cm².

∴ the total surface area is

$$\begin{aligned} A &= 2x^2 + 4x(x + 1) \\ &= 2x^2 + 4x^2 + 4x \\ &= (6x^2 + 4x) \text{ cm}^2 \end{aligned}$$

b $6x^2 + 4x = 240$

$$\therefore 3x^2 + 2x - 120 = 0$$

$$\therefore (3x + 20)(x - 6) = 0$$

$$\therefore x = -\frac{20}{3} \text{ or } 6$$

but $x > 0$, so $x = 6$

∴ the box is 6 cm × 6 cm × 7 cm.

- 7** Suppose the tinplate was x cm × x cm.

When 3 cm × 3 cm squares are cut from the corners, the base of the open box formed is $(x - 6)$ cm × $(x - 6)$ cm.

The open box has height 3 cm, so its volume is $3 \times (x - 6) \times (x - 6) = 80$

$$\therefore 3(x^2 - 12x + 36) = 80$$

$$3x^2 - 36x + 108 = 80$$

$$\therefore 3x^2 - 36x + 28 = 0$$

which has $a = 3$, $b = -36$, $c = 28$

$$\therefore x = \frac{-(-36) \pm \sqrt{(-36)^2 - 4(3)(28)}}{2(3)}$$

$$= \frac{36 \pm \sqrt{960}}{6} \text{ and since } x > 6,$$

$$x = 6 + \frac{\sqrt{960}}{6} \approx 11.16$$

∴ the original piece of tinplate was about 11.2 cm square.

8

Suppose one side of the rectangle has length x cm and the other has length y cm.

The perimeter is $(2x + 2y)$ cm,

$$\text{so } 2x + 2y = 20$$

$$\therefore 2y = 20 - 2x$$

$$\therefore y = 10 - x$$

The area of the rectangle is therefore

$$x(10 - x) \text{ cm}^2.$$

- 9** The smaller rectangle is similar to the original rectangle.

$$\therefore \frac{AB}{AD} = \frac{BC}{BY}$$

Suppose $AB = x$ units, and $AD = BC = 1$ unit

$$\therefore \frac{x}{1} = \frac{1}{x - 1}$$

$$\therefore x(x - 1) = 1$$

$$\therefore x^2 - x - 1 = 0$$

which has $a = 1$, $b = -1$, $c = -1$

If the area is 30 cm², then

$$x(10 - x) = 30$$

$$\therefore 10x - x^2 = 30$$

$$\therefore x^2 - 10x + 30 = 0$$

which has $a = 1$, $b = -10$, $c = 30$

$$\therefore x = \frac{-(-10) \pm \sqrt{(-10)^2 - 4(1)(30)}}{2(1)}$$

$$= \frac{10 \pm \sqrt{100 - 120}}{2}$$

$$= \frac{10 \pm \sqrt{-20}}{2}$$

∴ x has no real solutions, so it is not possible.

$$\therefore x = \frac{-(-1) \pm \sqrt{(-1)^2 - 4(1)(-1)}}{2(1)}$$

$$= \frac{1 \pm \sqrt{1 + 4}}{2}$$

$$= \frac{1 \pm \sqrt{5}}{2}$$

$$\therefore x = \frac{1 + \sqrt{5}}{2}, \text{ since } x > 0$$

But $x = \frac{AB}{AD}$, which is the golden ratio

$$\therefore \text{the golden ratio is } \frac{1 + \sqrt{5}}{2}.$$

- 10** Suppose the express train travels at x km h⁻¹. We know $\text{speed} = \frac{\text{distance}}{\text{time}}$, so $\text{time} = \frac{\text{distance}}{\text{speed}}$.

∴ it takes the express train $\frac{160}{x}$ hours and the normal train $\frac{160}{x - 10}$ hours.

$$\begin{aligned}\therefore \frac{160}{x} + \frac{1}{2} &= \frac{160}{x-10} \\ \therefore 160(x-10) + \frac{1}{2}x(x-10) &= 160x \\ \therefore 160x - 1600 + \frac{1}{2}x^2 - 5x &= 160x \\ \therefore x^2 - 10x - 3200 &= 0 \quad \text{which has } a=1, \quad b=-10, \quad c=-3200 \\ \therefore x &= \frac{-(-10) \pm \sqrt{(-10)^2 - 4(1)(-3200)}}{2(1)} = \frac{10 \pm \sqrt{12900}}{2} \\ \text{But } x > 0, \text{ so } x &= \frac{10 + \sqrt{12900}}{2} \approx 61.8 \text{ km h}^{-1} \\ \therefore \text{the express train travels on average at about } 61.8 \text{ km h}^{-1}.\end{aligned}$$

11 a

b The graph is a parabola.

c The maximum height reached by the ball is 21.25 m.

d Let $f(x) = ax^2 + bx + c$ be the form of the formula for height given horizontal distance x .

$$\begin{aligned}f(0) &= 1.25 \\ \therefore a(0)^2 + b(0) + c &= 1.25 \\ \therefore c &= 1.25 \\ \text{Also } f(5) &= 10 \\ \therefore a(5)^2 + b(5) + 1.25 &= 10 \\ \therefore 25a + 5b &= 8.75 \quad (1) \\ \text{And } f(15) &= 20 \\ \therefore a(15)^2 + b(15) + 1.25 &= 20 \\ \therefore 225a + 15b &= 18.75 \\ \therefore 75a + 5b &= 6.25 \quad \{\div 3\} \quad (2)\end{aligned}$$

Solving simultaneously (or using technology):

$$\begin{aligned}75a + 5b &= 6.25 \quad (2) \\ -25a - 5b &= -8.75 \quad -(1) \\ \hline 50a &= -2.5 \\ \therefore a &= -0.05 \\ \therefore -1.25 + 5b &= 8.75 \quad \{\text{substitute in (1)}\} \\ \therefore 5b &= 10 \\ \therefore b &= 2\end{aligned}$$

$$\text{So, } f(x) = -0.05x^2 + 2x + 1.25$$

e The ball bounces when it hits the ground

$$\begin{aligned}\therefore f(x) &= 0 \\ \therefore -0.05x^2 + 2x + 1.25 &= 0 \\ \text{Using technology, } x &= -0.616 \text{ or } x = 40.6 \\ \text{But } x \geq 0 \quad \therefore \text{ball bounces at } 40.6 \text{ m.}\end{aligned}$$

But Badrani is 40 m from Abiola, so the ball will reach Badrani before it bounces.

12 a The parabola has vertex (0, 8), so it has equation

$$\begin{aligned}y &= a(x-0)^2 + 8 \\ \therefore y &= ax^2 + 8 \\ \text{When } x = 3, y = 0, \text{ so} \\ 0 &= a(3^2) + 8 \\ \therefore 9a &= -8 \\ \therefore a &= -\frac{8}{9}\end{aligned}$$

$$\therefore \text{the equation of the parabola is } y = -\frac{8}{9}x^2 + 8.$$

- b** The truck is 4 m wide, so we use the equation in **a** to find the width of the tunnel 5 m above ground level.

$$\text{When } y = 5, \quad -\frac{8}{9}x^2 + 8 = 5$$

$$\therefore -\frac{8}{9}x^2 = -3$$

$$\therefore x^2 = \frac{27}{8}$$

$$\therefore x = \pm\sqrt{\frac{27}{8}}$$

$$\therefore x \approx \pm 1.837$$

So, the tunnel is $2 \times 1.837 \approx 3.67$ m wide, 5 m above ground level. But the truck is 4 m wide.

$\therefore$ the truck will not fit through the tunnel.

EXERCISE 1H

- 1 a** For $y = x^2 - 2x$,

$$a = 1, \quad b = -2, \quad c = 0.$$

As $a > 0$, the shape is

$\therefore$ the minimum value occurs when

$$x = \frac{-b}{2a} = \frac{2}{2} = 1$$

$$\text{and } y = 1^2 - 2(1) = -1$$

$\therefore$ the minimum value of $y = x^2 - 2x$ is -1 , occurring when $x = 1$.

- b** For $y = 4x^2 - x + 5$,

$$a = 4, \quad b = -1, \quad c = 5.$$

As $a > 0$, the shape is

$\therefore$ the minimum value occurs when

$$x = \frac{-b}{2a} = \frac{1}{8}$$

$$\text{and } y = 4\left(\frac{1}{8}\right)^2 - \frac{1}{8} + 5$$

$$= \frac{1}{16} - \frac{1}{8} + 5$$

$$= 4\frac{15}{16}$$

$\therefore$ the minimum value of $y = 4x^2 - x + 5$ is $4\frac{15}{16}$, occurring when $x = \frac{1}{8}$.

- c** For $y = 7x - 2x^2$,

$$a = -2, \quad b = 7, \quad c = 0.$$

As $a < 0$, the shape is

$\therefore$ the maximum value occurs when

$$x = \frac{-b}{2a} = \frac{-7}{-4} = \frac{7}{4}$$

$$\text{and } y = 7\left(\frac{7}{4}\right) - 2\left(\frac{7}{4}\right)^2$$

$$= \frac{49}{4} - \frac{49}{8}$$

$$= \frac{49}{8} \text{ or } 6\frac{1}{8}$$

$\therefore$ the maximum value of $y = 7x - 2x^2$ is $6\frac{1}{8}$, occurring when $x = \frac{7}{4}$.

- 2 a** For $P = -3x^2 + 240x - 800$,

$$a = -3, \quad b = 240, \quad c = -800.$$

As $a < 0$, the shape is

$\therefore$ the maximum profit occurs when

$$x = \frac{-b}{2a} = \frac{-240}{-6} = 40$$

$\therefore$ 40 refrigerators should be made each day to maximise the total profit.

- b** $P = -3(40)^2 + 240(40) - 800$

$$= 4000$$

$\therefore$ the maximum profit is \$4000.

- 3 a** Let the other side be y m long.
The perimeter is 200 m.

$$\begin{aligned}\therefore 2x + 2y &= 200 \\ \therefore x + y &= 100 \\ \therefore y &= 100 - x \\ \therefore \text{the area } A &= xy \\ \therefore A &= x(100 - x) \\ \therefore A &= 100x - x^2\end{aligned}$$

- b** $A = 100x - x^2$ is a quadratic function with $a = -1$, $b = 100$, $c = 0$.

As $a < 0$, the shape is 

$\therefore$ the area is maximised when

$$x = \frac{-b}{2a} = \frac{-100}{-2} = 50$$

and $y = 100 - 50 = 50$

$\therefore$ the area of the rectangle is maximised when $x = y = 50$, which is when the rectangle is a square.

- 4** Let the dimensions of the paddock be x m $\times$ y m.

If 1000 m of fence is available, then

$$2x + y = 1000 \quad \{\text{perimeter}\}$$

$$\therefore y = 1000 - 2x \quad \dots (1)$$

The area of the enclosure $A = xy$

$$\begin{aligned}\text{Since } y &= 1000 - 2x, \quad A = x(1000 - 2x) \\ &= 1000x - 2x^2\end{aligned}$$

$$\therefore A = -2x^2 + 1000x$$

A is a quadratic and $a < 0$, so its shape is 

So, area is maximised when $x = \frac{-b}{2a} = \frac{-1000}{2 \times (-2)} = 250$

and when $x = 250$, $y = 1000 - 2(250) = 500$

$\therefore$ the paddock has a maximum area when the dimensions are 250 m $\times$ 500 m.

The length of fence required for this enclosure is $9x + 8y$. If 1800 m is available for this enclosure, then $9x + 8y = 1800$.

- c** The area is a quadratic function with $a < 0$, so its shape is 

So, at $x = \frac{-b}{2a}$ we have a maximum

$$\therefore x = \frac{-225}{2 \times (-\frac{9}{8})} = 100, \quad \text{and when } x = 100, \quad y = \frac{1800 - 9(100)}{8} = 112.5$$

Hence, the area is maximised when the dimensions are 100 m $\times$ 112.5 m.

- b** If $9x + 8y = 1800$, then $y = \frac{1800 - 9x}{8}$.

The area of each pen is $A = xy$.

Substituting $y = \frac{1800 - 9x}{8}$ into A we get

$$A = x \left(\frac{1800 - 9x}{8} \right)$$

$$\therefore A = \frac{1800x}{8} - \frac{9x^2}{8}$$

$$\therefore A = -\frac{9}{8}x^2 + 225x \text{ m}^2$$

- 6 a** The graphs of $y = x^2 - 3x$ and $y = 2x - x^2$ meet where $x^2 - 3x = 2x - x^2$

$$\therefore 2x^2 - 5x = 0$$

$$\therefore x(2x - 5) = 0$$

$$\therefore x = 0 \text{ or } 2\frac{1}{2}$$

- b** The vertical separation between the curves is given by

$$S = (2x - x^2) - (x^2 - 3x) \quad \{y = 2x - x^2 \text{ is above } y = x^2 - 3x \text{ for } 0 \leq x \leq 2\frac{1}{2}\}$$

$$\therefore S = 2x - x^2 - x^2 + 3x$$

$$\therefore S = -2x^2 + 5x$$

Thus S is a quadratic function with $a < 0$ so the shape is

$$\therefore \text{ the maximum separation occurs when } x = \frac{-b}{2a} = \frac{-5}{-4} = \frac{5}{4}$$

$$\text{and } S = -2\left(\frac{5}{4}\right)^2 + 5\left(\frac{5}{4}\right)$$

$$= -\frac{25}{8} + \frac{25}{4} = \frac{25}{8} \text{ or } 3\frac{1}{8}$$

$\therefore \frac{7}{x} = \frac{x}{2x - 2}$

$\therefore 7(2x - 2) = x^2$

$\therefore 14x - 14 = x^2$

$\therefore x^2 - 14x + 14 = 0$

which has $a = 1$, $b = -14$ and $c = 14$

$\therefore x = \frac{-(-14) \pm \sqrt{(-14)^2 - 4(1)(14)}}{2(1)} = \frac{14 \pm \sqrt{140}}{2}$

Now $x - 2 > 0$, so $x = \frac{14 + \sqrt{140}}{2} \approx 12.92$ cm

$\therefore$ $[AB]$ is approximately 12.9 cm long.

- 8 a** The total length of wire for the fence is 60 m.

$$\therefore AB + BC + CD = 60$$

Since the enclosure is rectangular,

$$CD = AB$$

$$\therefore 2AB + x = 60$$

$$\therefore 2AB = 60 - x$$

$$\therefore AB = 30 - \frac{1}{2}x$$

$\therefore$ the area of the rectangle is

$$\begin{aligned} A &= x \left(30 - \frac{1}{2}x \right) \\ &= \left(30x - \frac{1}{2}x^2 \right) \text{ m}^2 \end{aligned}$$

b $A = 30x - \frac{1}{2}x^2$

has $a = -\frac{1}{2}$ and $b = 30$.

Since $a < 0$, A has a maximum at the axis of symmetry, and this is at

$$x = -\frac{b}{2a} = -\frac{30}{2(-\frac{1}{2})} = 30$$

When $x = 30$, $AB = 30 - \frac{1}{2} \times 30 = 15 \text{ m}$

$\therefore$ the enclosure is 15 m by 30 m.

9 a $y = 2x^2 + 4x - 1$

has $a = 2$, $b = 4$, $c = -1$

The axis of symmetry is $x = -\frac{b}{2a}$

$$\therefore x = -\frac{4}{2 \times 2}$$

$$\therefore x = -1$$

c When $x = 0$, $y = -1$,
so the y -intercept is -1 .

When $y = 0$, $2x^2 + 4x - 1 = 0$

$$\begin{aligned} \therefore x &= \frac{-4 \pm \sqrt{4^2 - 4(2)(-1)}}{2(2)} \\ &= \frac{-4 \pm \sqrt{24}}{4} \\ &= \frac{-4 \pm 2\sqrt{6}}{4} \\ &= -1 \pm \frac{1}{2}\sqrt{6} \end{aligned}$$

$\therefore$ the x -intercepts are $-1 \pm \frac{1}{2}\sqrt{6}$.

- b** When $x = -1$, $y = 2(-1)^2 + 4(-1) - 1 = 2 - 4 - 1 = -3$
 $\therefore$ the vertex is $(-1, -3)$

- 10** Since the container has a square base, the original tinplate must have been square.

Suppose its side was x cm long, so the base of the container is $(x - 8)$ cm by $(x - 8)$ cm.

The height of the container is 4 cm, so its capacity is $4(x - 8)(x - 8) \text{ cm}^3$.

$$\therefore 4(x - 8)^2 = 120$$

$$\therefore (x - 8)^2 = 30$$

$$\therefore x - 8 = \pm\sqrt{30}$$

$$\therefore x = 8 \pm \sqrt{30}$$

Clearly, $x > 8$, so $x = 8 + \sqrt{30} \approx 13.48$

$\therefore$ the tinplate was about 13.5 cm by 13.5 cm.

11 a $-x^2 - 5x + 3 = x^2 + 3x + 11$

$$\therefore 2x^2 + 8x + 8 = 0$$

$$\therefore x^2 + 4x + 4 = 0$$

$$\therefore (x + 2)^2 = 0$$

$$\therefore x = -2$$

b From **a**, $x^2 + 3x + 11 = -x^2 - 5x + 3$ has only one solution.

$\therefore$ the lines touch but do not cross.

So $y = x^2 + 3x + 11$ is either above or below $y = -x^2 - 5x + 3$ for all $x \neq -2$.

If $x = 1$, $(1)^2 + 3(1) + 11 = 15$ and $-(1)^2 - 5(1) + 3 = -3$

$\therefore x^2 + 3x + 11 > -x^2 - 5x + 3$ for $x \neq -2$.

12 a $y = 3x^2 + 4x + 7$
has $a = 3$, $b = 4$, and $c = 7$
Since $a > 0$,
the graph
has shape

and so has a minimum.

This occurs on the axis of symmetry

$$x = -\frac{b}{2a}$$

$$\therefore x = -\frac{4}{2(3)} = -\frac{2}{3}$$

When $x = -\frac{2}{3}$,

$$\begin{aligned} y &= 3\left(-\frac{2}{3}\right)^2 + 4\left(-\frac{2}{3}\right) + 7 \\ &= \frac{4}{3} - \frac{8}{3} + 7 \\ &= \frac{17}{3} = 5\frac{2}{3} \end{aligned}$$

$\therefore$ the minimum is $5\frac{2}{3}$ when $x = -\frac{2}{3}$

b $y = -2x^2 - 5x + 2$
has $a = -2$, $b = -5$, and $c = 2$
Since $a < 0$,
the graph
has shape

and so has a maximum.

This occurs on the axis of symmetry

$$x = -\frac{b}{2a}$$

$$\therefore x = -\frac{-5}{2(-2)} = -\frac{5}{4}$$

When $x = -\frac{5}{4}$,

$$\begin{aligned} y &= -2\left(-\frac{5}{4}\right)^2 - 5\left(-\frac{5}{4}\right) + 2 \\ &= -\frac{25}{8} + \frac{25}{4} + 2 \\ &= \frac{-25 + 50 + 16}{8} \\ &= \frac{41}{8} = 5\frac{1}{8} \end{aligned}$$

$\therefore$ the maximum is $5\frac{1}{8}$ when $x = -\frac{5}{4}$

13 a The total length of fencing is $(8x + 9y)$ m

$$\therefore 8x + 9y = 600$$

$$\therefore 9y = 600 - 8x$$

$$\therefore y = \frac{600 - 8x}{9}$$

The area of each pen is

$$A = xy$$

$$= x \left(\frac{600 - 8x}{9} \right) \text{ m}^2$$

c The maximum area of each pen is

$$\begin{aligned} &37\frac{1}{2} \times 33\frac{1}{3} \\ &= \frac{75}{2} \times \frac{100}{3} \\ &= 1250 \text{ m}^2 \end{aligned}$$

b $A = x \left(\frac{600 - 8x}{9} \right)$

$$= \frac{600}{9}x - \frac{8}{9}x^2$$

which has $a = -\frac{8}{9}$, $b = \frac{600}{9}$

Since $a < 0$, A is maximised at the axis of

symmetry, which is $x = -\frac{b}{2a}$

$$\therefore x = -\frac{\frac{600}{9}}{2\left(-\frac{8}{9}\right)} = \frac{600}{16}$$

$$\therefore x = \frac{75}{2}$$

$$\text{When } x = \frac{75}{2}, y = \frac{600 - 8\left(\frac{75}{2}\right)}{9} = 33\frac{1}{3}$$

$\therefore$ for maximum area, each pen should be $37\frac{1}{2}$ m $\times$ $33\frac{1}{3}$ m.

14 a $9x^2 - kx + 4$ touches the x -axis if

$$\Delta = 0$$

$$\therefore (-k)^2 - 4(9)(4) = 0$$

$$\therefore k^2 - 144 = 0$$

$$\therefore k = \pm 12$$

b The functions intersect when

$$9x^2 - 12x + 4 = 9x^2 + 12x + 4$$

$$\therefore 24x = 0$$

$$\therefore x = 0$$

$$f(0) = 9(0)^2 - 12(0) + 4 = 4$$

The two functions intersect at $(0, 4)$.

REVIEW SET 1C

1 a The axis of symmetry is $x = 2$.

b When $x = 2$, $y = \frac{1}{2}(2 - 2)^2 - 4$
 $= -4$

$\therefore$ the vertex is $(2, -4)$

c When $x = 0$, $y = \frac{1}{2}(-2)^2 - 4$
 $= -2$

$\therefore$ the y -intercept is -2

2 a $x^2 - 5x - 3 = 0$

has $a = 1$, $b = -5$, $c = -3$

$$\therefore x = \frac{-(-5) \pm \sqrt{(-5)^2 - 4(1)(-3)}}{2(1)}$$

$$= \frac{5}{2} \pm \frac{\sqrt{37}}{2}$$

b $2x^2 - 7x - 3 = 0$

has $a = 2$, $b = -7$, $c = -3$

$$\therefore x = \frac{-(-7) \pm \sqrt{(-7)^2 - 4(2)(-3)}}{2(2)}$$

$$= \frac{7}{4} \pm \frac{\sqrt{73}}{4}$$

3 a $x^2 - 7x + 3 = 0$

has $a = 1$, $b = -7$, $c = 3$

$$\therefore x = \frac{-(-7) \pm \sqrt{(-7)^2 - 4(1)(3)}}{2(1)}$$

$$= \frac{7 \pm \sqrt{49 - 12}}{2}$$

$$= \frac{7 \pm \sqrt{37}}{2}$$

$$\therefore x = \frac{7}{2} \pm \frac{\sqrt{37}}{2}$$

b $2x^2 - 5x + 4 = 0$

has $a = 2$, $b = -5$, $c = 4$

$$\therefore x = \frac{-(-5) \pm \sqrt{(-5)^2 - 4(2)(4)}}{2(2)}$$

$$= \frac{5 \pm \sqrt{25 - 32}}{4}$$

$$\therefore x = \frac{5 \pm \sqrt{-7}}{4}$$

$\therefore x$ has no real solutions.

4 a The graph has vertex $(2, -20)$, so its equation is

$$y = a(x - 2)^2 - 20 \text{ for some } a \neq 0.$$

Now an x -intercept is 5

$$\therefore a(5 - 2)^2 - 20 = 0$$

$$\therefore 9a = 20$$

$$\text{and so } a = \frac{20}{9}$$

So, the equation is $y = \frac{20}{9}(x - 2)^2 - 20$.

c The graph has vertex $(-3, 0)$, so its equation is $y = a(x + 3)^2$ for some $a \neq 0$.

The y -intercept is 2

$$\therefore a(3)^2 = 2$$

$$\therefore 9a = 2$$

$$\text{and so } a = \frac{2}{9}$$

So, the equation is $y = \frac{2}{9}(x + 3)^2$.

b Since one x -intercept is 7 and the axis of symmetry is $x = 4$, the other x -intercept is $x = 1$.

$\therefore$ the graph has equation

$$y = a(x - 7)(x - 1) \text{ for some } a \neq 0.$$

The y -intercept is -2

$$\therefore a(-7)(-1) = -2$$

$$\therefore a = -\frac{2}{7}$$

$\therefore$ the equation is $y = -\frac{2}{7}(x - 7)(x - 1)$.

$$\begin{aligned}
 \mathbf{5} \quad \mathbf{a} \quad & y = 2x^2 + 3x - 7 \\
 & \text{has } a = 2, \quad b = 3, \quad c = -7 \\
 \therefore \quad \Delta &= b^2 - 4ac \\
 &= 3^2 - 4(2)(-7) \\
 &= 65
 \end{aligned}$$

Since $\Delta > 0$, the graph cuts the x -axis twice.

Note that since $a > 0$, the graph is

$$\begin{aligned}
 \mathbf{b} \quad & y = -3x^2 - 7x + 4 \\
 & \text{has } a = -3, \quad b = -7, \quad c = 4 \\
 \therefore \quad \Delta &= b^2 - 4ac \\
 &= (-7)^2 - 4(-3)4 \\
 &= 97
 \end{aligned}$$

Since $\Delta > 0$, the graph cuts the x -axis twice.

Note that since $a < 0$, the graph is

$$\begin{aligned}
 \mathbf{6} \quad \mathbf{a} \quad & y = -2x^2 + 3x + 2 \\
 & \text{has } a = -2, \quad b = 3, \quad c = 2 \\
 \therefore \quad \Delta &= b^2 - 4ac \\
 &= 3^2 - 4(-2)(2) \\
 &= 25
 \end{aligned}$$

Since $\Delta > 0$, the function is neither positive definite nor negative definite.

$$\begin{aligned}
 \mathbf{b} \quad & y = 3x^2 + x + 11 \\
 & \text{has } a = 3, \quad b = 1, \quad c = 11 \\
 \therefore \quad \Delta &= b^2 - 4ac \\
 &= 1^2 - 4(3)(11) \\
 &= -131
 \end{aligned}$$

$\therefore \Delta < 0$, and since $a > 0$, the function is positive definite.

7 The quadratic has vertex $(2, 25)$.

$\therefore$ its equation is $y = a(x - 2)^2 + 25$

The y -intercept is 1, so $a(-2)^2 + 25 = 1$

$$\therefore 4a = -24$$

$$\therefore a = -6$$

$\therefore$ the equation is $y = -6(x - 2)^2 + 25$

8 Let the line with gradient -3 and y -intercept c have equation $y = -3x + c$.

$y = -3x + c$ is tangential to $y = 2x^2 - 5x + 1$ if they meet at exactly one point.

$y = 2x^2 - 5x + 1$ meets $y = -3x + c$ when $2x^2 - 5x + 1 = -3x + c$

$$\therefore 2x^2 - 2x + 1 - c = 0$$

The graphs meet exactly once when this equation has a repeated root $\therefore \Delta = 0$

$$\therefore (-2)^2 - 4(2)(1 - c) = 0$$

$$\therefore 4 - 8 + 8c = 0$$

$$\therefore 8c = 4$$

$$\therefore c = \frac{1}{2}$$

$\therefore$ the y -intercept of the line is $\frac{1}{2}$.

$$\begin{aligned}
 \mathbf{9} \quad & y = x^2 - 2x + k \\
 & \text{has } a = 1, \quad b = -2, \quad c = k \\
 \therefore \quad \Delta &= b^2 - 4ac \\
 &= (-2)^2 - 4(1)k \\
 &= 4 - 4k
 \end{aligned}$$

The graph cuts the x -axis twice if $\Delta > 0$

$$\therefore 4 - 4k > 0$$

$$\therefore 4k < 4$$

$$\therefore k < 1$$

10 The x -intercepts are 3 and -2 , so the equation is $y = a(x - 3)(x + 2)$ for some $a \neq 0$.

But the y -intercept is 24 $\therefore a(-3)(2) = 24$

$$\therefore -6a = 24$$

$$\therefore a = -4$$

$\therefore$ the equation is $y = -4(x - 3)(x + 2)$

$$\therefore y = -4(x^2 - x - 6)$$

$$\therefore y = -4x^2 + 4x + 24$$

- 11** $y = mx - 10$ is a tangent to $y = 3x^2 + 7x + 2$ if they meet at exactly one point (touch).
 $y = 3x^2 + 7x + 2$ meets $y = mx - 10$ when $3x^2 + 7x + 2 = mx - 10$
 $\therefore 3x^2 + (7 - m)x + 12 = 0$

The graphs meet exactly once when this equation has a repeated root $\therefore \Delta = 0$

$$\therefore (7 - m)^2 - 4(3)(12) = 0$$

$$\therefore 49 - 14m + m^2 - 144 = 0$$

$$\therefore m^2 - 14m - 95 = 0$$

$$\therefore (m + 5)(m - 19) = 0$$

$$\therefore m = -5 \text{ or } 19$$

- 12** $ax^2 + [3 - a]x - 4 = 0$ will have roots which are real and positive if:

(1) $\Delta \geq 0$

(2) sum of roots > 0

(3) product of roots > 0

(1) $\Delta \geq 0$

$$\therefore (3 - a)^2 - 4(a)(-4) \geq 0$$

$$\therefore 9 - 6a + a^2 + 16a \geq 0$$

$$\therefore a^2 + 10a + 9 \geq 0$$

$$\therefore (a + 9)(a + 1) \geq 0$$

$(a + 9)(a + 1)$ has sign diagram

$$\therefore \Delta \geq 0 \text{ when } a \leq -9 \text{ or } a \geq -1$$

(2) sum of roots > 0

$$\therefore -\frac{3 - a}{a} > 0$$

$-\frac{3 - a}{a}$ has sign diagram

$$\therefore \text{sum of roots} > 0 \text{ when } a < 0 \text{ or } a > 3$$

(3) product of roots > 0

$$\therefore \frac{-4}{a} > 0$$

$-\frac{4}{a}$ has sign diagram

$$\therefore \text{product of roots} > 0 \text{ when } a < 0$$

$\therefore$ the only values of a which satisfy all three conditions are $a \leq -9$ and $-1 \leq a < 0$.

- 13 a i** The quadratic has x -intercepts ± 3 , so its equation is

$$y = a(x + 3)(x - 3) \text{ for some } a \neq 0.$$

Its y -intercept is -27 , so

$$a(3)(-3) = -27$$

$$\therefore -9a = -27$$

$$\therefore a = 3$$

$$\therefore \text{the equation is } y = 3(x + 3)(x - 3)$$

$$\text{or } y = 3x^2 - 27$$

- ii** The straight line has

$$\text{gradient } \frac{0 - (-27)}{3 - 0} = 9$$

and its y -intercept is -27 .

So, its equation is $y = 9x - 27$.

- b** From the graph, the straight line is above the curve when $0 < x < 3$.

- 14** $y = -5x + k$ meets $y = x^2 - 3x + c$ when $x^2 - 3x + c = -5x + k$
 $\therefore x^2 + 2x + c - k = 0$

For $y = -5x + k$ to be a tangent to $y = x^2 - 3x + c$, this equation must have exactly one solution, so there is a repeated root.

$$\therefore \Delta = 0$$

$$\therefore 2^2 - 4(1)(c - k) = 0$$

$$\therefore 4 = 4(c - k)$$

$$\therefore c - k = 1$$

15 The roots of $4x^2 - 3x - 3 = 0$ are p and q .

$$\therefore \text{sum of roots} = -\frac{-3}{4} \quad \text{and} \quad \therefore \text{product of roots} = \frac{-3}{4}$$

$$\therefore p + q = \frac{3}{4} \quad \therefore pq = -\frac{3}{4}$$

Now consider a quadratic equation with roots p^3 and q^3 .

$$\begin{aligned} \text{sum of roots} &= p^3 + q^3 & \text{product of roots} &= p^3 \times q^3 \\ &= (p + q)^3 - 3p^2q - 3pq^2 & &= (pq)^3 \\ &= (p + q)^3 - 3pq(p + q) & &= \left(-\frac{3}{4}\right)^3 \\ &= \left(\frac{3}{4}\right)^3 - 3\left(-\frac{3}{4}\right)\left(\frac{3}{4}\right) & &= -\frac{27}{64} \\ &= \frac{27}{64} + \frac{27}{16} \\ &= \frac{135}{64} \end{aligned}$$

$$\therefore \text{a quadratic equation } ax^2 + bx + c = 0 \text{ with roots } p^3 \text{ and } q^3 \text{ has } -\frac{b}{a} = \frac{135}{64} \text{ and } \frac{c}{a} = -\frac{27}{64}$$

$$\therefore b = -\frac{135}{64}a \text{ and } c = -\frac{27}{64}a$$

$$\therefore \text{the quadratic equation is } ax^2 - \frac{135}{64}ax - \frac{27}{64}a = 0, \quad a \neq 0$$

$$\therefore a\left(x^2 - \frac{135}{64}x - \frac{27}{64}\right) = 0, \quad a \neq 0$$

$$\therefore a(64x^2 - 135x - 27) = 0, \quad a \neq 0$$

FUNCTIONS

EXERCISE 2A

- 1
 - a $\{(1, 3), (2, 4), (3, 5), (4, 6)\}$ is a function since no two ordered pairs have the same x -coordinate.
 - b $\{(1, 3), (3, 2), (1, 7), (-1, 4)\}$ is not a function since two of the ordered pairs, $(1, 3)$ and $(1, 7)$, have the same x -coordinate 1.
 - c $\{(2, -1), (2, 0), (2, 3), (2, 11)\}$ is not a function since each ordered pair has the same x -coordinate 2.
 - d $\{(7, 6), (5, 6), (3, 6), (-4, 6)\}$ is a function since no two ordered pairs have the same x -coordinate.
 - e $\{(0, 0), (1, 0), (3, 0), (5, 0)\}$ is a function since no two ordered pairs have the same x -coordinate.
 - f $\{(0, 0), (0, -2), (0, 2), (0, 4)\}$ is not a function since each ordered pair has the same x -coordinate 0.

- 2
 - a  Each line cuts the graph no more than once, so it is a function.
 - b  Each line cuts the graph no more than once, so it is a function.
 - c  Each line cuts the graph no more than once, so it is a function.
 - d  Some lines cut the graph more than once, so it is not a function.
 - e  Each line cuts the graph no more than once, so it is a function.
 - f  The lines cut the graph more than once, so it is not a function.
 - g  Each line cuts the graph no more than once, so it is a function.
 - h  One line cuts the graph more than once, so it is not a function.
 - i  Each line cuts the graph no more than once, so it is a function.

- 3 The graph of a straight line is not a function if the graph is a vertical line. So, it is not a function if it has the form $x = a$ for some constant a .
The vertical line through $x = a$ cuts the graph at every point, so it is not a function.

- 4 $x^2 + y^2 = 9$ is the equation of a circle, centre (0, 0) and radius 3.

Now $x^2 + y^2 = 9$

$$\therefore y^2 = 9 - x^2$$

$$\therefore y = \pm\sqrt{9 - x^2}$$

For any value of x where $-3 < x < 3$, y has two real values. Hence $x^2 + y^2 = 9$ is not a function.

$$\text{b } G(x) = \frac{2x + 3}{x - 4} \text{ is undefined when } x - 4 = 0 \\
 \therefore x = 4$$

So, when $x = 4$, $G(x)$ does not exist.

$$\text{c } G(x + 2) = \frac{2(x + 2) + 3}{(x + 2) - 4} = \frac{2x + 4 + 3}{x + 2 - 4} = \frac{2x + 7}{x - 2}$$

$$\begin{array}{l}

 \therefore 2x + 3 = -3x + 12 \\
 \therefore 5x = 9 \text{ and so } x = \frac{9}{5}

7 f is the function which converts x into $f(x)$ whereas $f(x)$ is the value of the function at any value of x .

$$\begin{array}{l}

 \text{then } 9650 - 860t = 5780 \\
 \therefore 860t = 3870 \\
 \therefore t = 4.5
 \end{array}$$

The value of the photocopier is 5780 euros after $4\frac{1}{2}$ years.

$$\begin{array}{l}
 \text{c } \text{Original purchase price is when } t = 0, \\
 V(0) = 9650 - 860(0) \\

The original purchase price was 9650 euros.

9

First sketch the linear function which passes through the two points (2, 1) and (5, 3).

Then sketch two quadratic functions which also pass through the two points.

$$\text{10 } f(x) = ax + b \text{ where } f(2) = 1 \text{ and } f(-3) = 11$$

$$\text{So, } a(2) + b = 1 \quad \text{and} \quad a(-3) + b = 11$$

$$\therefore 2a + b = 1 \quad \therefore -3a + b = 11$$

$$\therefore b = 1 - 2a \quad \dots (1) \quad \therefore b = 11 + 3a \quad \dots (2)$$

$$\text{Solving (1) and (2) simultaneously, } 1 - 2a = 11 + 3a$$

$$\therefore 5a = -10$$

$$\therefore a = -2$$

Substituting $a = -2$ into (1) gives $b = 1 - 2(-2) = 5$. So, $a = -2$, $b = 5$.

Hence $f(x) = -2x + 5$

11 $f(x) = ax + \frac{b}{x}$ where $f(1) = 1$ and $f(2) = 5$

So, $a(1) + \frac{b}{1} = 1$ and $a(2) + \frac{b}{2} = 5$
 $\therefore a + b = 1$
 $\therefore a = 1 - b$ (1)

$\therefore 2a + \frac{b}{2} = 5$ (2)

Substituting (1) into (2), $2(1 - b) + \frac{b}{2} = 5$

$\therefore 2 - 2b + \frac{b}{2} = 5$

$\therefore -\frac{3b}{2} = 3$

$\therefore b = -2$

Substituting $b = -2$ into (1) gives $a = 1 - (-2) = 3$.

So, $a = 3$, $b = -2$.

12 $T(x) = ax^2 + bx + c$ where $T(0) = -4$, $T(1) = -2$, and $T(2) = 6$

So, $a(0)^2 + b(0) + c = -4$
 $\therefore c = -4$

Also, $a(1)^2 + b(1) + c = -2$ and $a(2)^2 + b(2) + c = 6$
 $\therefore a + b + c = -2$ and $\therefore 4a + 2b + c = 6$

Substituting $c = -4$ into both equations gives

$a + b + (-4) = -2$ and $4a + 2b + (-4) = 6$
 $\therefore a + b = 2$ $\therefore 4a + 2b = 10$ (2)
 $\therefore a = 2 - b$ (1)

Substituting (1) into (2) gives $4(2 - b) + 2b = 10$ $\therefore 8 - 4b + 2b = 10$
 $\therefore -2b = 2$
 $\therefore b = -1$

Substituting $b = -1$ into (1) gives $a = 2 - (-1) = 3$.

$\therefore a = 3$, $b = -1$, and $c = -4$. So, $T(x) = 3x^2 - x - 4$.

$$\therefore a(-x)^2 + b(-x) + c = ax^2 + bx + c$$

$$\therefore \cancel{ax^2} - bx + \cancel{c} = \cancel{ax^2} + bx + \cancel{c}$$

$$\therefore -b = b \quad \{\text{equating coefficients of } x\}$$

$$\therefore b = 0$$

b If $g(x) = ax^3 + bx^2 + cx + d$, $a \neq 0$ is an odd function, then $g(-x) = -g(x)$

$$\therefore a(-x)^3 + b(-x)^2 + c(-x) + d = -(ax^3 + bx^2 + cx + d)$$

$$\therefore a(-1)^3x^3 + bx^2 - cx + d = -ax^3 - bx^2 - cx - d$$

$$\therefore -ax^3 + bx^2 - cx + d = -ax^3 - bx^2 - cx - d$$

$$\text{Equating coefficients of } x^3: \quad -a = -a$$

$$\therefore a \in \mathbb{R}, a \neq 0$$

$$\text{Equating coefficients of } x: \quad -c = -c$$

$$\therefore c \in \mathbb{R}$$

$$\text{Equating coefficients of } x^2: \quad b = -b$$

$$\therefore b = 0$$

$$\text{Equating constant terms:} \quad d = -d$$

$$\therefore d = 0$$

So, the cubic function $g(x) = ax^3 + bx^2 + cx + d$, $a \neq 0$ is an odd function when $b = 0$, $d = 0$.

c If $h(x) = ax^4 + bx^3 + cx^2 + dx + e$, $a \neq 0$ is an even function, then $h(-x) = h(x)$

$$\therefore a(-x)^4 + b(-x)^3 + c(-x)^2 + d(-x) + e = ax^4 + bx^3 + cx^2 + dx + e$$

$$\therefore ax^4 - bx^3 + cx^2 - dx + e = ax^4 + bx^3 + cx^2 + dx + e$$

$$\text{Equating coefficients of } x^4: \quad a = a$$

$$\therefore a \in \mathbb{R}, a \neq 0$$

$$\text{Equating coefficients of } x: \quad -d = d$$

$$\therefore d = 0$$

$$\text{Equating coefficients of } x^3: \quad -b = b$$

$$\therefore b = 0$$

$$\text{Equating constant terms:} \quad e = e$$

$$\therefore e \in \mathbb{R}$$

$$\text{Equating coefficients of } x^2: \quad c = c$$

$$\therefore c \in \mathbb{R}$$

So, the quartic function $h(x) = ax^4 + bx^3 + cx^2 + dx + e$, $a \neq 0$ is an even function when $b = 0$, $d = 0$.

- 7 a** Suppose $h(x) = f(x) + g(x)$ where $f(x)$ and $g(x)$ are even functions.

$$\begin{aligned}\text{Now } h(-x) &= f(-x) + g(-x) \\ &= f(x) + g(x) \quad \{f(x) \text{ and } g(x) \text{ are even functions}\} \\ &= h(x) \text{ for all } x \\ \therefore h(x) &\text{ is even.}\end{aligned}$$

Thus the sum of two even functions is an even function.

- b** Suppose $h(x) = f(x) - g(x)$ where $f(x)$ and $g(x)$ are odd functions.

$$\begin{aligned}\text{Now } h(-x) &= f(-x) - g(-x) \\ &= -f(x) - (-g(x)) \quad \{f(x) \text{ and } g(x) \text{ are odd functions}\} \\ &= -(f(x) - g(x)) \\ &= -h(x) \\ \therefore h(x) &\text{ is odd.}\end{aligned}$$

Thus the difference between two odd functions is an odd function.

- c** Suppose $h(x) = f(x)g(x)$ where $f(x)$ and $g(x)$ are odd functions.

$$\begin{aligned}\text{Now } h(-x) &= f(-x)g(-x) \\ &= -f(x) \times -g(x) \quad \{f(x) \text{ and } g(x) \text{ are odd functions}\} \\ &= f(x)g(x) \\ &= h(x) \\ \therefore h(x) &\text{ is even.}\end{aligned}$$

Thus the product of two odd functions is an even function.

- 8** $f(x)$ is an even function and $g(x)$ is an odd function.

$$\begin{aligned}(f \circ g)(-x) &= f(g(-x)) \\ &= f(-g(x)) \quad \{g(x) \text{ is an odd function}\} \\ &= f(g(x)) \quad \{f(x) \text{ is an even function}\} \\ &= (f \circ g)(x)\end{aligned}$$

So $(f \circ g)(x)$ is an even function.

$$\text{So, } \frac{x+4}{2x-1} > 0 \text{ when } x < -4 \text{ and } x > \frac{1}{2}.$$

- c** The graphs of $y_1 = \frac{2}{2x-5}$ and $y_2 = \frac{1}{x+7}$ do not intersect.
 $y_1 = \frac{2}{2x-5}$ has vertical asymptote $x = 2.5$ and $y_2 = \frac{1}{x+7}$ has vertical asymptote $x = -7$.
 So, $\frac{2}{2x-5} < \frac{1}{x+7}$ when $-7 < x < 2.5$.

- d** The graphs of $y_1 = \frac{x^2+5x}{x^2-4}$ and $y_2 = 0$ intersect at $x = -5$ and $x = 0$.
 $y_1 = \frac{x^2+5x}{x^2-4}$ has vertical asymptotes $x = -2$ and $x = 2$.

- e** The graphs of $y_1 = \frac{2x-3}{x+2}$ and $y_2 = \frac{2x}{x-2}$ intersect at $x \approx 0.545$.
 $y_1 = \frac{2x-3}{x+2}$ has vertical asymptote $x = -2$ and $y_2 = \frac{2x}{x-2}$ has vertical asymptote $x = 2$.
 So, $\frac{2x-3}{x+2} < \frac{2x}{x-2}$ when $-2 < x < 0.545$ and $x > 2$.

 $y_1 = \frac{x+6}{2x-5}$ has vertical asymptote $x = 2.5$.
 So, $\frac{x+6}{2x-5} > 2x+3$ when $x < -1.75$ and $2.5 < x < 3$.

- 3 a** The graphs of $y_1 = x^3$ and $y_2 = x$ intersect at $x = -1$, $x = 0$, and $x = 1$.

- b** The graphs of $y_1 = x^3 - 2x^2 + 6$ and $y_2 = 5x$ intersect at $x = -2$, $x = 1$, and $x = 3$.
So, $x^3 - 2x^2 + 6 < 5x$ when $x < -2$ and $1 < x < 3$.

- c** The graphs of $y_1 = x^3 - 6$ and $y_2 = 2x - 3x^2$ intersect at $x = -3$, $x \approx -1.41$, and $x \approx 1.41$.
So, $x^3 - 6 \leq 2x - 3x^2$ when $x \leq -3$ and $-1.41 \leq x \leq 1.41$.

Now $xy \leq |x||y|$

$$\therefore x^2 + 2xy + y^2 \leq x^2 + 2|x||y| + y^2$$

$$\therefore |x + y|^2 \leq (|x| + |y|)^2$$

$$\therefore |x + y| \leq |x| + |y| \quad \{\text{both sides} \geq 0\}$$

$\therefore$ the statement is true for all x, y .

b

$$|x - y|^2 = (x - y)^2$$

$$= x^2 - 2xy + y^2$$

and $(|x| - |y|)^2 = |x|^2 - 2|x||y| + |y|^2$

$$= x^2 - 2|x||y| + y^2$$

Now $xy \leq |x||y|$

$$\therefore -2xy \geq -2|x||y|$$

$$\therefore x^2 - 2xy + y^2 \geq x^2 - 2|x||y| + y^2$$

$$\therefore |x - y|^2 \geq (|x| - |y|)^2$$

$$\therefore |x - y| \geq |x| - |y| \quad \{\text{both sides} \geq 0\}$$

$\therefore$ the statement is true for all x, y .

EXERCISE 2I

- 1 a i** $f : x \mapsto \frac{3}{x-2}$ is undefined when $x = 2$, so $x = 2$ is a vertical asymptote.
 As $|x| \rightarrow \infty$, $f(x) \rightarrow 0$, so $y = 0$ is a horizontal asymptote.
- ii** Domain is $\{x \mid x \neq 2\}$, Range is $\{y \mid y \neq 0\}$

- iii $f(0) = \frac{3}{0-2} = -\frac{3}{2}$
 So, the y -intercept is $-\frac{3}{2}$.
 $f(x) = 0$ when $\frac{3}{x-2} = 0$,
 which has no solutions.
 $\therefore$ there is no x -intercept.

- iv As $x \rightarrow 2^-$, $y \rightarrow -\infty$.
 As $x \rightarrow 2^+$, $y \rightarrow \infty$.
 As $x \rightarrow \infty$, $y \rightarrow 0^+$.
 As $x \rightarrow -\infty$, $y \rightarrow 0^-$.

- b i $f(x) = 2 - \frac{3}{x+1}$ is undefined when $x = -1$, so $x = -1$ is a vertical asymptote.
 As $|x| \rightarrow \infty$, $\frac{3}{x+1} \rightarrow 0$, so $f(x) \rightarrow 2 \therefore y = 2$ is a horizontal asymptote.

- ii Domain is $\{x \mid x \neq -1\}$, Range is $\{y \mid y \neq 2\}$

- iii $f(0) = 2 - \frac{3}{0+1} = -1$
 So, the y -intercept is -1 .
 $f(x) = 0$ when $2 - \frac{3}{x+1} = 0$
 $\therefore \frac{3}{x+1} = 2$
 $\therefore x+1 = \frac{3}{2}$
 $\therefore x = \frac{1}{2}$

So, the x -intercept is $\frac{1}{2}$.

- iv As $x \rightarrow -1^-$, $y \rightarrow \infty$.
 As $x \rightarrow -1^+$, $y \rightarrow -\infty$.
 As $x \rightarrow \infty$, $y \rightarrow 2^-$.
 As $x \rightarrow -\infty$, $y \rightarrow 2^+$.

- c i $f : x \mapsto \frac{x+3}{x-2}$ is undefined when $x = 2$, so $x = 2$ is a vertical asymptote.

$$\text{Now } f(x) = \frac{x+3}{x-2} = \frac{1 + \frac{3}{x}}{1 - \frac{2}{x}}$$

$\therefore$ as $|x| \rightarrow \infty$, $f(x) \rightarrow \frac{1}{1} = 1$, and so $y = 1$ is a horizontal asymptote.

- ii Domain is $\{x \mid x \neq 2\}$, Range is $\{y \mid y \neq 1\}$

- iii $f(0) = \frac{0+3}{0-2} = -\frac{3}{2}$
 So, the y -intercept is $-\frac{3}{2}$.
 $f(x) = 0$ when $\frac{x+3}{x-2} = 0$
 $\therefore x+3 = 0$
 $\therefore x = -3$

So, the x -intercept is -3 .

- iv As $x \rightarrow 2^-$, $y \rightarrow -\infty$.
 As $x \rightarrow 2^+$, $y \rightarrow \infty$.
 As $x \rightarrow \infty$, $y \rightarrow 1^+$.
 As $x \rightarrow -\infty$, $y \rightarrow 1^-$.

- d i** $f(x) = \frac{3x-1}{x+2}$ is undefined when $x = -2$, so $x = -2$ is a vertical asymptote.

$$f(x) = \frac{3x-1}{x+2} = \frac{3 - \frac{1}{x}}{1 + \frac{2}{x}}$$

As $|x| \rightarrow \infty$, $f(x) \rightarrow \frac{3}{1} = 3$ and so $y = 3$ is a horizontal asymptote.

- ii** Domain is $\{x \mid x \neq -2\}$, Range is $\{y \mid y \neq 3\}$

iii $f(0) = \frac{3(0)-1}{0+2} = -\frac{1}{2}$

So, the y -intercept is $-\frac{1}{2}$.

$$f(x) = 0 \quad \text{when} \quad \frac{3x-1}{x+2} = 0$$

$$\therefore 3x-1 = 0$$

$$\therefore x = \frac{1}{3}$$

So, the x -intercept is $\frac{1}{3}$.

- iv** As $x \rightarrow -2^-$, $y \rightarrow \infty$.

As $x \rightarrow -2^+$, $y \rightarrow -\infty$.

As $x \rightarrow \infty$, $y \rightarrow 3^-$.

As $x \rightarrow -\infty$, $y \rightarrow 3^+$.

- 2 a** The function is defined when $cx + d \neq 0$, or when $x \neq -\frac{d}{c}$.

So, the domain is $\{x \mid x \neq -\frac{d}{c}\}$.

- b** The equation of the vertical asymptote is $x = -\frac{d}{c}$.

- c** To find the horizontal asymptote of $y = \frac{ax+b}{cx+d}$, we consider the function's behavior as $|x| \rightarrow \infty$.

$$\begin{aligned} \text{Now for } c \neq 0, \quad \frac{ax+b}{cx+d} &= \frac{acx+bc}{c(cx+d)} \\ &= \frac{a(cx+d) + bc - ad}{c(cx+d)} \\ &= \frac{a}{c} + \frac{bc-ad}{c(cx+d)} \\ &= \frac{a}{c} + \frac{b - \frac{ad}{c}}{cx+d} \end{aligned}$$

$\therefore$ as $|x| \rightarrow \infty$, $y \rightarrow \frac{a}{c}$, and so $y = \frac{a}{c}$ is a horizontal asymptote.

EXERCISE 2J

- iii** f is $y = 3x + 1$
so f^{-1} is $x = 3y + 1$

 $\therefore f^{-1}(x)$ passes through $(\frac{1}{2}, 0)$ and $(0, -2)$

$$f^{-1}(x) \text{ has gradient } \frac{-2 - 0}{0 - \frac{1}{2}} = \frac{-2}{-\frac{1}{2}} = 4$$

$$\text{So, its equation is } \frac{y - 0}{x - \frac{1}{2}} = 4$$

$$\text{which is } y = 4x - 2$$

$$\text{So, } f^{-1}(x) = 4x - 2$$

iii f is $y = \frac{x+2}{4}$

so f^{-1} is $x = \frac{y+2}{4}$

$$\therefore 4x = y + 2$$

$$\therefore y = 4x - 2. \quad \text{So, } f^{-1}(x) = 4x - 2$$

2 a i

f is $y = 2x + 5$

so f^{-1} is $x = 2y + 5$

$$\therefore x - 5 = 2y$$

$$\therefore y = \frac{x-5}{2}$$

So, $f^{-1}(x) = \frac{x-5}{2}$

$f(x)$ passes through $(0, 5)$ and $(-\frac{5}{2}, 0)$

$\therefore f^{-1}(x)$ passes through $(5, 0)$ and $(0, -\frac{5}{2})$.

 $= 2\left(\frac{x-5}{2}\right) + 5$
 $= x - 5 + 5$
 $= x$

b i

f is $y = \frac{3-2x}{4}$

so f^{-1} is $x = \frac{3-2y}{4}$

$$\therefore 4x = 3 - 2y$$

$$\therefore 4x - 3 = -2y$$

$$\therefore y = -2x + \frac{3}{2}$$

So, $f^{-1}(x) = -2x + \frac{3}{2}$

ii

$f(x)$ passes through $(0, \frac{3}{4})$ and $(\frac{3}{2}, 0)$

$\therefore f^{-1}(x)$ passes through $(\frac{3}{4}, 0)$ and $(0, \frac{3}{2})$.

 $= \frac{3 + 4x - 3}{4}$
 $= \frac{4x}{4}$
 $= x$

c i f is $y = x + 3$
so f^{-1} is $x = y + 3$
 $\therefore y = x - 3$
So, $f^{-1}(x) = x - 3$

iii $(f^{-1} \circ f)(x) = f^{-1}(f(x))$
 $= f^{-1}(x + 3)$
 $= (x + 3) - 3$

and $(f \circ f^{-1})(x) = f(f^{-1}(x))$

- 4 a** Domain of $f(x)$ is $\{x \mid -2 \leq x \leq 0\}$
b Range of $f(x)$ is $\{y \mid 0 \leq y \leq 5\}$
c Domain of $f^{-1}(x)$ is $\{x \mid 0 \leq x \leq 5\}$
d Range of $f^{-1}(x)$ is $\{y \mid -2 \leq y \leq 0\}$
- 5 a** The functions in **3 e** and **3 f** are self-inverse functions.
- b** Any linear function of the form $y = a - x$ will be a self-inverse function, for example $y = -x$ (where $a = 0$):
- c** Any rational function of the form $y = \frac{a}{x}$ will be a self-inverse function, for example $y = \frac{2}{x}$ (where $a = 2$):

6 f is $y = 2x - 5$

$\therefore$ the inverse function is $x = 2y - 5$

$$\therefore 2y = x + 5$$

$$\therefore y = \frac{x + 5}{2}$$

$$\therefore f^{-1}(x) = \frac{x + 5}{2}$$

To find $(f^{-1})^{-1}(x)$, we need to find the inverse function for $y = \frac{x + 5}{2}$

This is $x = \frac{y + 5}{2}$

$$\therefore 2x = y + 5$$

$$\therefore y = 2x - 5$$

This is the original function $f(x)$.

So, $(f^{-1})^{-1}(x) = f(x)$.

- 7**
- a** For $\{(1, 2), (2, 4), (3, 5)\}$, there is at most one x -value corresponding to each y -value, so the function has an inverse. The inverse function is $\{(2, 1), (4, 2), (5, 3)\}$.
 - b** For $\{(-1, 3), (0, 2), (1, 3)\}$, there are two x -values corresponding to the y -value of 3. So, the function does not have an inverse.
 - c** For $\{(2, 1), (-1, 0), (0, 2), (1, 3)\}$, there is at most one x -value corresponding to each y -value, so the function has an inverse. The inverse function is $\{(0, -1), (1, 2), (2, 0), (3, 1)\}$.
 - d** For $\{(-1, -1), (0, 0), (1, 1)\}$, there is at most one x -value corresponding to each y -value, so the function has an inverse. The inverse function is $\{(-1, -1), (0, 0), (1, 1)\}$.

8 **a**

b Using the 'horizontal line test', f does not have an inverse function as a horizontal line through $y = x^2 - 4$ cuts it more than once.

c For $x \geq 0$, any horizontal line cuts it only once.
 $\therefore f$ does have an inverse function for $x \geq 0$;
 $f^{-1}(x) = \sqrt{x + 4}$.

9

10 $f(x) = \frac{1}{x}$ has inverse function $x = \frac{1}{y}$ or $y = \frac{1}{x}$

So, $f^{-1}(x) = \frac{1}{x}$, which means $f(x)$ is a self-inverse function.

11 **a** $f(x) = \frac{3x - 8}{x - 3}$ has graph

The vertical line test shows it to be a function.

Symmetry about $y = x$ shows it is a self-inverse function.

$$\begin{aligned}
 \mathbf{b} \quad f(x) &= \frac{3x-8}{x-3} \text{ has inverse function } x = \frac{3y-8}{y-3} \\
 \therefore x(y-3) &= 3y-8 \\
 \therefore xy-3x &= 3y-8 \\
 \therefore xy-3y &= 3x-8 \\
 \therefore y(x-3) &= 3x-8 \\
 \therefore y &= \frac{3x-8}{x-3} \\
 \therefore f^{-1}(x) &= \frac{3x-8}{x-3}
 \end{aligned}$$

So, $f(x) = f^{-1}(x)$, which means $f(x)$ is a self-inverse function.

- 12 a** If $y = f(x)$ has an inverse function, then the inverse function must also be a function. Thus, it must satisfy the ‘vertical line test’, i.e., no vertical line can cut it more than once. This condition for the inverse function cannot be satisfied if the original function does not satisfy the ‘horizontal line test’. Thus, the ‘horizontal line test’ is a valid test for the existence of an inverse function.

b i This graph satisfies the ‘horizontal line test’ and therefore has an inverse function.

ii, iii These graphs both fail the ‘horizontal line test’ so neither of these have inverse functions.

c ii Domain $\{x \mid x \geq 1\}$ or $\{x \mid x \leq 1\}$ **iii** Domain $\{x \mid x \geq 1\}$ or $\{x \mid x \leq -2\}$

13 a f is $y = x^2, x \leq 0$
 so f^{-1} is $x = y^2, y \leq 0$
 $\therefore y = -\sqrt{x}$
 So, $f^{-1}(x) = -\sqrt{x}$

$f : x \mapsto x^2 - 4x + 3$ satisfies the ‘vertical line test’ so is therefore a function. It does not however satisfy the horizontal line test as any horizontal line above the vertex cuts the graph twice. Therefore it does not have an inverse function.

- b i** For $g(x) = x^2 - 4x + 3$ where $x \geq 2$, all horizontal lines cut the graph no more than once. Therefore $g(x)$ has an inverse function for $x \geq 2$.

ii g is $y = x^2 - 4x + 3, x \geq 2$

so g^{-1} is $x = y^2 - 4y + 3, y \geq 2$

$$\therefore x = (y-2)^2 - 4 + 3$$

$$\therefore x = (y-2)^2 - 1$$

$$\therefore x+1 = (y-2)^2$$

$$\therefore y-2 = \sqrt{x+1}, y \geq 2, x \geq -1$$

$$\therefore y = 2 + \sqrt{1+x}, y \geq 2, x \geq -1$$

So, $g^{-1}(x) = 2 + \sqrt{1+x}$ as required.

iii A Domain of g is $\{x \mid x \geq 2\}$.

Range is $\{y \mid y \geq -1\}$

B Domain of g^{-1} is

 $\therefore g^{-1}(-1) = 8 - 2(-1) = 10$

c $(f \circ g^{-1})(x) = 9$
 $\therefore f(g^{-1}(x)) = 9$
 $\therefore f(8 - 2x) = 9$
 $\therefore 2(8 - 2x) + 5 = 9$
 $\therefore 16 - 4x + 5 = 9$
 $\therefore -4x = -12$
 $\therefore x = 3$

b f is $y = 2x + 5$
 so f^{-1} is $x = 2y + 5$
 $\therefore 2y = x - 5$
 $\therefore y = \frac{x-5}{2}$
 So, $f^{-1}(x) = \frac{x-5}{2}$
 $\therefore f^{-1}(-3) = \frac{-3-5}{2} = \frac{-8}{2} = -4$ and $g^{-1}(6) = 8 - 2 \times 6 = 8 - 12 = -4$
 $\therefore f^{-1}(-3) - g^{-1}(6) = -4 - (-4) = -4 + 4 = 0$ as required

So, $f^{-1}(x) = f(x)$ is true for parts **b**, **c**, **d**, and **e**.

- 20**
- a** $f(x)$ passes through $A(x, f(x))$, so $f^{-1}(x)$ passes through $B(f(x), x)$.
 - b** Substituting the coordinates of $B(f(x), x)$ into $y = f^{-1}(x)$ gives $f^{-1}(f(x)) = x$.
 - c** B has coordinates $(x, f^{-1}(x))$ since it lies on $y = f^{-1}(x)$,
so A has coordinates $(f^{-1}(x), x)$ as $f(x)$ is the inverse of $f^{-1}(x)$.
Substituting the coordinates of $A(f^{-1}(x), x)$ into $y = f(x)$ gives $x = f(f^{-1}(x))$.

 As $x \rightarrow -2^+$, $y \rightarrow -\infty$
 $\therefore$ the vertical asymptote is $x = -2$.
 On $x \in \mathbb{R}$, $y = \frac{1-x^2}{(x+2)^2}$ has horizontal asymptote $y = -1$, but we are only considering the function on the domain $-5 \leq x \leq 5$.

- b** Graphing $y = -2x^4 + 5x^2 + x + 2$ on $-2 \leq x \leq 2$ using technology:
- i** The higher of the two maxima $(1.17, 6.27)$ is the global maximum on $-2 \leq x \leq 2$, so the maximum value is 6.27.
 - ii** The global maximum on $-2 \leq x \leq 0$ occurs at the lower maximum $(-1.06, 4.03)$, so the maximum value on this interval is 4.03.
 - iii** The higher maximum $(1.17, 6.27)$ is in $0 \leq x \leq 2$, so the maximum value on this interval is 6.27.

 $\therefore x = \frac{1}{2}$

b $f(x) = \sqrt{x+7}$
 is undefined when $x + 7 < 0$
 $\therefore x < -7$

4 a $f(x) = x(x+4)(3x+1)$ is
 zero when $x = 0, -4,$ and $-\frac{1}{3}$.
 When $x = 10, y = 10(14)(31) = 4340 > 0$.
 The factors are single, so the signs alternate.

$\therefore$ sign diagram is: $\begin{array}{c} - & + & - & + \\ -4 & -\frac{1}{3} & 0 & \end{array} x$

b $f(x) = \frac{-11}{(x+1)(x+8)}$ is
 undefined when $x = -1$ or -8 .
 When $x = 0, y = \frac{-11}{(1)(8)} = -\frac{11}{8} < 0$.
 The factors are single, so the signs alternate.

 $\therefore x = 2$

$$5 = a(0)^2 + b(0) + c$$

$$\therefore -4 = 9a + 6a - 24 + 5$$

$$\therefore 15 = 15a \quad \text{and so } a = 1$$

$$\text{Now, substituting } a = 1 \text{ into (2) gives } b = 2(1) - 8 = -6$$

$$\begin{array}{ll}

$$\begin{array}{ll}

Hence, $(f^{-1} \circ h^{-1})(x) = (h \circ f)^{-1}(x)$ as required.

 \end{array}$$

$$\begin{array}{l}

 \therefore (g \circ f^{-1})(3) = \left(\frac{3 - 11}{2}\right)^2 \\
 = (-4)^2 = 16
 \end{array}$$

14 The domain is $\{x \mid x \neq 4\}$, so $x = 4$ is a vertical asymptote.

The range is $\{y \mid y \neq -1\}$, so $y = -1$ is a horizontal asymptote.

We now consider the behaviour of the function near the asymptotes, using the sign diagram

As $x \rightarrow \infty$, $y \rightarrow -1$

As $x \rightarrow -\infty$, $y \rightarrow -1$

Note that we cannot tell whether the function tends to -1 from above or below.

As $x \rightarrow 4^-$, $y \rightarrow \infty$

As $x \rightarrow 4^+$, $y \rightarrow -\infty$

So, the function could be:

(Note: There may be other answers.)

15 a, d

b Any horizontal line through the graph cuts it no more than once. Therefore it has an inverse function.

c $g(x) = x^2 + 6x + 7, \quad x \leq -3$

$\therefore y = x^2 + 6x + 7, \quad x \leq -3$

$\therefore g^{-1}(x)$ is $x = y^2 + 6y + 7, \quad y \leq -3$

$= (y + 3)^2 - 9 + 7$

$\therefore x + 2 = (y + 3)^2$

$\therefore y + 3 = \pm \sqrt{x + 2}$

$\therefore y = -3 \pm \sqrt{x + 2}$

but $y \leq -3$, so $y = -3 - \sqrt{x + 2}$

So, $g^{-1}(x) = -3 - \sqrt{x + 2}, \quad x \geq -2$

d The range of g is $\{y \mid y \geq -2\}$.

e The domain of g^{-1} is $\{x \mid x \geq -2\}$, and the range of g^{-1} is $\{y \mid y \leq -3\}$.

16 a x -intercept is 2.61, y -intercept is 4.29 {using technology}

b $(-0.973, 4.47)$ is a local maximum

c As $x \rightarrow 4^-$, $y \rightarrow -\infty$

As $x \rightarrow 4^+$, $y \rightarrow \infty$

$\therefore$ the vertical asymptote is $x = 4$.

As $x \rightarrow \infty$, $y \rightarrow 7^+$

As $x \rightarrow -\infty$, $y \rightarrow 3^+$

$\therefore$ the horizontal asymptotes are $y = 3$ and $y = 7$.

d Domain is $\{x \mid x \neq 4\}$.

Range is $\{y \mid y \leq 4.47, y > 7\}$.

EXERCISE 3G.1

1 a When $t = 0$, $W_0 = 100$ grams = the initial weight

- b i** When $t = 4$, $W_4 = 100 \times 2^{0.1 \times 4} = 100 \times 2^{0.4} \approx 132$ grams
- ii** When $t = 10$, $W_{10} = 100 \times 2^1 = 200$ grams

- iii** When $t = 24$, $W_{24} = 100 \times 2^{0.1 \times 24} = 100 \times 2^{2.4} \approx 528$ grams

2 a $P_0 = 50$ (the initial population)

- b i** When $n = 2$, $P_2 = 50 \times 2^{0.3 \times 2} = 50 \times 2^{0.6} \approx 75.785$
So, the expected population is 76 possums.
- ii** When $n = 5$, $P_5 = 50 \times 2^{0.3 \times 5} = 50 \times 2^{1.5} \approx 141.421$
So, the expected population is 141 possums.

- iii** When $n = 10$, $P_{10} = 50 \times 2^{0.3 \times 10} = 50 \times 2^3 = 400$
So, the expected population is 400 possums.

3 a $B_0 = 6$ pairs = 12 bears

- b** In 2018, $t = 20$
 $\therefore B_{20} = 12 \times 2^{0.18 \times 20} = 12 \times 2^{3.6} \approx 145.509 \approx 146$ bears

- c** In 2008, $t = 10$
 $\therefore \% \text{ increase} = \left(\frac{B_{20} - B_{10}}{B_{10}} \right) \times 100\%$
 $= \left(\frac{12 \times 2^{3.6} - 12 \times 2^{1.8}}{12 \times 2^{1.8}} \right) \times 100\%$
 $= \left(\frac{2^{3.6} - 2^{1.8}}{2^{1.8}} \right) \times 100\%$
 $\approx 248\%$

4 a i When $t = 0$, $V_0 = V_0 \times 2^0 = V_0$
So, the speed is V_0 .

- ii** When $t = 20$, $V_{20} = V_0 \times 2^{0.05 \times 20} = V_0 \times 2^1 = 2V_0$
So, the speed is $2V_0$.

b V_0 becomes $2V_0$. So, there was a 100% increase in speed.

$$\begin{aligned} \text{c } \left(\frac{V_{50} - V_{20}}{V_{20}} \right) \times 100\% &= \left(\frac{V_0 \times 2^{2.5} - V_0 \times 2^1}{V_0 \times 2^1} \right) \times 100\% \\ &= \left(\frac{2^{2.5} - 2^1}{2^1} \right) \times 100\% \\ &\approx 183\% \end{aligned}$$

This expression is the percentage increase in speed from the speed at 20°C to the speed at 50°C .
($V_{50} - V_{20}$ is the increase in speed.)

EXERCISE 3G.2

1 $W(t) = 250 \times (0.998)^t$ grams

a $W(0) = 250 \times (0.998)^0$
 $= 250 \times 1 = 250$ grams $\therefore$ 250 g of radioactive substance was put aside.

b i When $t = 400$,
 $W(400)$
 $= 250 \times (0.998)^{400}$
 ≈ 112 grams

ii When $t = 800$,
 $W(800)$
 $= 250 \times (0.998)^{800}$
 ≈ 50.4 grams

iii When $t = 1200$,
 $W(1200)$
 $= 250 \times (0.998)^{1200}$
 ≈ 22.6 grams

d When $W(t) = 125$
 $250 \times (0.998)^t = 125$
 $\therefore (0.998)^t = 0.5$
 $\therefore t \approx 346.2$ {using technology}
 It takes approximately 346 years.

2 $T(t) = 100 \times 2^{-0.02t}$

a $T(0) = 100 \times 2^0$
 $= 100 \times 1$
 $= 100^\circ\text{C}$

b i $T(15) = 100 \times 2^{-0.02 \times 15}$
 $= 100 \times 2^{-0.3}$
 $\approx 81.2^\circ\text{C}$

ii $T(20) = 100 \times 2^{-0.02 \times 20}$
 $= 100 \times 2^{-0.4}$
 $\approx 75.8^\circ\text{C}$

iii $T(78) = 100 \times 2^{-0.02 \times 78}$
 $= 100 \times 2^{-1.56}$
 $\approx 33.9^\circ\text{C}$

3 a i $T(0) = -10 + 32 \times 2^0$
 $= -10 + 32 \times 1 = 22^\circ\text{C}$

ii $T(5) = -10 + 32 \times 2^{-0.2 \times 5}$
 $= -10 + 32 \times 2^{-1} = 6^\circ\text{C}$

iii $T(10) = -10 + 32 \times 2^{-0.2 \times 10}$
 $= -10 + 32 \times 2^{-2} = -2^\circ\text{C}$

iv $T(15) = -10 + 32 \times 2^{-0.2 \times 15}$
 $= -10 + 32 \times 2^{-3} = -6^\circ\text{C}$

c $32 \times 2^{-0.2t}$ is always > 0 since 2^t is always > 0
 $\therefore -10 + 32 \times 2^{-0.2t}$ is always > -10
 $\therefore$ the temperature of the packet of peas will never reach -10°C .

4 $W_t = 1000 \times 2^{-0.03t}$

a $W_0 = 1000 \times 2^0$
 $= 1000 \times 1$
 $= 1000 \text{ g}$

b i W_{10}
 $= 1000 \times 2^{-0.3}$
 $\approx 812 \text{ g}$

ii W_{100}
 $= 1000 \times 2^{-3}$
 $= 125 \text{ g}$

iii W_{1000}
 $= 1000 \times 2^{-30}$
 $\approx 9.31 \times 10^{-7} \text{ g}$

d When $W_t = 10$, $1000 \times 2^{-0.03t} = 10$
 $\therefore (2^{-0.03})^t = 0.01$
 $\therefore t \approx 221.46 \text{ \{using technology\}}$

There is 10 g of the substance remaining after approximately 221 years.

e Initial weight $= W_0 = 1000 \text{ g}$
Amount remaining after t years $= W_t = 1000 \times 2^{-0.03t}$
Amount that has decayed after t years $= W_0 - W_t$
 $= 1000 - 1000 \times 2^{-0.03t}$
 $= 1000(1 - 2^{-0.03t}) \text{ g}$

5 a When $t = 0$, $W_0 = W_0 2^0$
 $= W_0 \text{ grams}$
 $\therefore$ the original weight was W_0 grams.

c $W_0 \times 2^{-0.0002t} = \frac{1}{512} W_0$
 $\therefore (2^{-0.0002})^t = \frac{1}{512}$
 $\therefore t = 45\,000 \text{ \{using technology\}}$
It would take 45 000 years.

b % change $= \left(\frac{W_{1000} - W_0}{W_0} \right) \times 100\%$
 $= \left(\frac{W_0 \times 2^{-0.2} - W_0}{W_0} \right) \times 100\%$
 $= (2^{-0.2} - 1) \times 100\%$
 $\approx -12.9\%$

The weight loss was about 12.9%.

c i When $A_n = 10\,000$, $2000 \times e^{0.57n} = 10\,000$
 $\therefore e^{0.57n} = 5$
 $\therefore \ln e^{0.57n} = \ln 5$
 $\therefore 0.57n = \ln 5$
 $\therefore n = \frac{\ln 5}{0.57}$
 $\therefore n \approx 2.82$

$\therefore$ it takes about 2.82 weeks for the infested area to reach 10 000 hectares.

4 $r = 107.5\% = 1.075$, $u_1 = 160\,000$,
 $u_{n+1} = 250\,000$

$$\begin{aligned} u_{n+1} &= u_1 \times r^n \\ \therefore 250\,000 &= 160\,000 \times (1.075)^n \\ \therefore (1.075)^n &= \frac{25}{16} \\ \therefore \log(1.075)^n &= \log\left(\frac{25}{16}\right) \\ \therefore n \log(1.075) &= \log\left(\frac{25}{16}\right) \\ \therefore n &= \frac{\log\left(\frac{25}{16}\right)}{\log(1.075)} \approx 6.1709 \end{aligned}$$

$\therefore$ it would take 6.17 years or 6 years 62 days.

7 $M_t = 1000e^{-0.04t}$ $\therefore M_0 = 1000e^0 = 1000$ g

a For M_t to halve, $M_t = 500$
 $\therefore 1000e^{-0.04t} = 500$
 $\therefore e^{-0.04t} = 0.5$
 $\therefore -0.04t = \ln(0.5)$
 $\therefore t = \frac{\ln(0.5)}{-0.04}$
 $\therefore t \approx 17.3$ years

b For $M_t = 25$ g,
 $\therefore 1000e^{-0.04t} = 25$
 $\therefore e^{-0.04t} = 0.025$
 $\therefore -0.04t = \ln(0.025)$
 $\therefore t = \frac{\ln(0.025)}{-0.04}$
 $\therefore t \approx 92.2$ years

c For $M_t = 1\%$ of M_0

$$\therefore 1000e^{-0.04t} = 0.01 \times 1000$$

$$\therefore e^{-0.04t} = 0.01$$

$$\therefore -0.04t = \ln(0.01)$$

$$\therefore t = \frac{\ln(0.01)}{-0.04}$$

$$\therefore t \approx 115 \text{ years}$$

8 $V = 50(1 - e^{-0.2t}) \text{ ms}^{-1}$

So, when $V = 40$, $50(1 - e^{-0.2t}) = 40$

$$\therefore 1 - e^{-0.2t} = 0.8$$

$$\therefore e^{-0.2t} = 0.2$$

$$\therefore -0.2t = \ln(0.2)$$

$$\therefore -\frac{1}{5}t = \ln\left(\frac{1}{5}\right)$$

$$\therefore -\frac{1}{5}t = \ln(5^{-1})$$

$$\therefore -\frac{1}{5}t = -\ln 5$$

$$\therefore t = 5 \ln 5$$

$\therefore$ it will take $5 \ln 5$ seconds for the man's speed to reach 40 ms^{-1} .

b When $P(t) = 20\,000$,

$$1000 \times 2^t = 20\,000$$

$$\therefore 2^t = 20$$

$$\therefore \log 2^t = \log 20$$

$$\therefore t \log 2 = \log 20$$

$$\therefore t = \frac{\log 20}{\log 2} \approx 4.32$$

$\therefore$ it will take 4.32 weeks for the population to reach 20 000 mice.

$$\therefore -0.04t \log 2 = \log W - \log 1000$$

$$\therefore 0.04t \log 2 = 3 - \log W$$

$$\therefore t = \frac{3 - \log W}{0.04 \log 2}$$

c i When $W = 20$,

$$t = \frac{3 - \log 20}{0.04 \log 2} \approx 141$$

$\therefore$ it will take about 141 years for the weight to reach 20 grams.

ii When $W = 0.001$,

$$t = \frac{3 - \log(0.001)}{0.04 \log 2} \approx 498$$

$\therefore$ it will take about 498 years for the weight to reach 0.001 grams.

12 $W = W_0 \times 2^{-0.0002t}$ grams**a** When W is 25% of original,

$$W = \frac{1}{4} \text{ of } W_0$$

$$\therefore W_0 \times 2^{-0.0002t} = \frac{1}{4} \times W_0$$

$$\therefore 2^{-0.0002t} = 2^{-2}$$

$$\therefore 0.0002t = 2$$

$$\therefore t = \frac{2}{0.0002}$$

$$\therefore t = 10\,000$$

$\therefore$ it would take 10 000 years.

b When W is 0.1% of original,

$$W = \frac{0.1}{100} \text{ of } W_0$$

$$\therefore W_0 \times 2^{-0.0002t} = \frac{1}{1000} \times W_0$$

$$I = 10\% \text{ of } I_0$$

$$\therefore I_0 \times 2^{-0.02t} = 0.1 \times I_0$$

$$\therefore 2^{-0.02t} = 0.1$$

$$\therefore \log 2^{-0.02t} = \log(0.1)$$

$$\therefore -0.02t \log 2 = \log(0.1)$$

$$\therefore -\frac{1}{50}t \log 2 = -1$$

$$\therefore t = \frac{50}{\log 2} \text{ seconds}$$

14 $V = 60(1 - 2^{-0.2t})$ ms⁻¹When $V = 50$, $60(1 - 2^{-0.2t}) = 50$

$$\therefore 2^{-0.2t} = 0.1\bar{6}$$

$$\therefore \log 2^{-0.2t} = \log 0.1\bar{6}$$

8 $P_t = P_0 \times 2^{\frac{t}{3}}, \quad t \geq 0$

When $t = 0$, $P_0 = P_0 \times 2^0 = P_0$. So the initial population was P_0 .

a If P_t doubles, $P_t = 2P_0$

$$\therefore P_0 2^{\frac{t}{3}} = 2P_0$$

$$\therefore 2^{\frac{t}{3}} = 2^1$$

$$\therefore \frac{t}{3} = 1$$

$$\therefore t = 3$$

So, it would take 3 years.

b % increase = $\left(\frac{P_4 - P_0}{P_0} \right) \times 100\%$

$$= \left(\frac{P_0 \times 2^{\frac{4}{3}} - P_0}{P_0} \right) \times 100\%$$

$$= (2^{\frac{4}{3}} - 1) \times 100\%$$

$$\approx 151.98\%$$

or $P_4 = P_0 \times 2^{\frac{4}{3}}$

$$\approx P_0 \times 2.52$$

$$\approx 252\% \text{ of } P_0$$

So, an increase of 152%.

So, the % increase is 152%.

9 a $g(x) = 2e^x - 5$ has inverse function $x = 2e^y - 5$

$$\therefore 2e^y = x + 5$$

$$\therefore e^y = \frac{x+5}{2}$$

$$\therefore y = \ln \left(\frac{x+5}{2} \right)$$

$$\therefore g^{-1}(x) = \ln \left(\frac{x+5}{2} \right)$$

c Domain of g is $\{x \mid x \in \mathbb{R}\}$, range is $\{y \mid y > -5\}$
Domain of g^{-1} is $\{x \mid x > -5\}$, range is $\{y \mid y \in \mathbb{R}\}$

d When $x = 0$, $y = 2e^0 - 5 = -3$
 $\therefore$ the y -intercept of g is -3 .

When $y = 0$, $2e^x - 5 = 0$

$$\therefore e^x = \frac{5}{2}$$

$$\therefore x = \ln \left(\frac{5}{2} \right)$$

$\therefore$ the x -intercept of g is $\ln \left(\frac{5}{2} \right) \approx 0.916$.

$\therefore g^{-1}$ has x -intercept -3 and y -intercept $\ln \left(\frac{5}{2} \right) \approx 0.916$.

As $x \rightarrow -\infty$, $y \rightarrow -5^+$

$\therefore$ the H.A. of g is $y = -5$.

$\therefore g^{-1}$ has V.A. $x = -5$.

10 a $g(5) = \ln(5+4)$

$$= \ln 9$$

$$\therefore (f \circ g)(5) = f(g(5))$$

$$= e^{\ln 9}$$

$$= 9$$

b $f(0) = e^0$

$$= 1$$

$$\therefore (g \circ f)(0) = g(f(0))$$

$$= \ln(1+4)$$

$$= \ln 5$$

10 a $f(x) = e^{x^2} - x^6$
 $\therefore f(-x) = e^{(-x)^2} - (-x)^6$
 $= e^{x^2} - x^6$
 $= f(x)$

So, $f(x)$ is an even function.

$g(x) = \ln(x^2 + 1)$
 $\therefore g(-x) = \ln((-x)^2 + 1)$
 $= \ln(x^2 + 1)$
 $= g(x)$

So, $g(x)$ is an even function.

On the domain $0 \leq x \leq 5$, the graphs intersect at $(1.25, 0.943)$ and $(2.14, 1.72)$.

c $x^6 - e^{x^2} + \ln(x^2 + 1) > 0$
 when $\ln(x^2 + 1) > e^{x^2} - x^6$
 $\therefore$ using **b**, $1.25 < x < 2.14$.

11 $g(x) = \log_3(x + 2) - 2$

a We require $x + 2 > 0$, so $x > -2$
 $\therefore$ the domain is $\{x \mid x > -2\}$ and the range is $\{y \mid y \in \mathbb{R}\}$.

b If $x \rightarrow -2^+$, $y \rightarrow -\infty$ $\therefore$ V.A. is $x = -2$.
 As $x \rightarrow \infty$, $y \rightarrow \infty$.

When $x = 0$, $g(0) = \log_3 2 - 2 \approx -1.37$ So, the y -intercept ≈ -1.37

When $y = 0$, $\log_3(x + 2) = 2$ $\therefore x + 2 = 3^2$
 $\therefore x = 7$ So, the x -intercept is 7.

c g^{-1} is defined by $x = \log_3(y + 2) - 2$
 $\therefore \log_3(y + 2) = x + 2$
 $\therefore y + 2 = 3^{x+2}$
 $\therefore y = 3^{x+2} - 2$
 $\therefore g^{-1}(x) = 3^{x+2} - 2$

Horizontal asymptote is $y = -2$.

Domain is $x \in \mathbb{R}$.

Range is $\{y \mid y > -2\}$.

12 $W_t = 8000 \times e^{-\frac{t}{20}}$ grams
 $W_0 = 8000e^0$

 $= 8000$ grams

a When $W_t = \frac{1}{2} \times 8000$ grams, $8000e^{-\frac{t}{20}} = 4000$
 $\therefore e^{-\frac{t}{20}} = 0.5$
 $\therefore -\frac{t}{20} = \ln(0.5)$
 $\therefore t = -20 \ln(0.5) \approx 13.9$ weeks

b When $W_t = 1000$ g,
 $8000e^{-\frac{t}{20}} = 1000$
 $\therefore e^{-\frac{t}{20}} = \frac{1}{8}$
 $\therefore -\frac{t}{20} = \ln(\frac{1}{8})$
 $\therefore t = -20 \ln(\frac{1}{8})$
 $\therefore t \approx 41.6$ weeks

c When $W_t = 0.1\%$ of W_0
 $= \frac{1}{1000} \times 8000 = 8$ g,
 $8000e^{-\frac{t}{20}} = 8$
 $\therefore e^{-\frac{t}{20}} = 0.001$
 $\therefore -\frac{t}{20} = \ln(0.001)$
 $\therefore t = -20 \ln(0.001) \approx 138$ weeks

EXERCISE 5B

1 a, b

- c
- i If $b > 0$, the function is translated vertically upwards through b units.
 - ii If $b < 0$, the function is translated vertically downwards $|b|$ units.

Summary: For $y = f(x) + b$, $y = f(x)$ is translated vertically through b units.
If $b > 0$ movement is vertically upwards b units.
If $b < 0$ movement is vertically downwards $|b|$ units.

a

b

Summary: For $y = f(x - a)$, $y = f(x)$ is translated horizontally through a units.
If $a > 0$ movement is to the right. If $a < 0$ movement is to the left.

6 A translation of 2 units right and 3 units down or $\begin{pmatrix} 2 \\ -3 \end{pmatrix}$.

7 To translate $f(x)$ 3 units right, we need to find $f(x - 3)$.

$$\begin{aligned}\therefore g(x) &= f(x - 3) \\ &= (x - 3)^2 - 2(x - 3) + 2 \\ &= x^2 - 6x + 9 - 2x + 6 + 2 \\ \therefore g(x) &= x^2 - 8x + 17\end{aligned}$$

8 a The transformation from $f(x) = x^2$ to $g(x) = (x - 3)^2 + 2$ is a translation of 3 units right and 2 units up.

i $(0, 0)$ is translated to $(3, 2)$.

ii $(-3, 9)$ is translated to $(0, 11)$.

iii $f(2) = 2^2 = 4$

$\therefore (2, 4)$ is translated to $(5, 6)$.

b The transformation from $g(x)$ back to $f(x)$ is a translation of $\begin{pmatrix} -3 \\ -2 \end{pmatrix}$.

i $(1, 6)$ is translated to $(-2, 4)$.

ii $(-2, 27)$ is translated to $(-5, 25)$.

iii $(1\frac{1}{2}, 4\frac{1}{4})$ is translated to $(-1\frac{1}{2}, 2\frac{1}{4})$.

EXERCISE 5D

- 1 a** If $f(x) = 3x$
then $-f(x) = -(3x)$
 $= -3x$
And $f(x) = 3x$
has inverse function
 $x = 3y$
 $\therefore y = \frac{1}{3}x$
 $\therefore f^{-1}(x) = \frac{1}{3}x$

- b** If $f(x) = e^x$

 $= -e^x$
And $f(x) = e^x$
has inverse function
 $x = e^y$
 $\therefore y = \ln x$
 $\therefore f^{-1}(x) = \ln x$

- c** If $f(x) = x^2$
then $-f(x) = -(x^2)$
 $= -x^2$
 $f(x) = x^2$ does not have an inverse function as it does not satisfy the horizontal line test.

then $-f(x) = -(\ln x)$
 $= -\ln x$
And $f(x) = \ln x$
has inverse function
 $x = \ln y$
 $\therefore y = e^x$
 $\therefore f^{-1}(x) = e^x$

then $-f(x) = -(x^3 - 2)$
 $= -x^3 + 2$
And $f(x) = x^3 - 2$
has inverse function
 $x = y^3 - 2$

 $\therefore g(x) = (-x)^4 - 2(-x)^3 - 3(-x)^2 + 5(-x) - 7$
 $= x^4 + 2x^3 - 3x^2 - 5x - 7$

5 a To transform $y = f(x)$ to $g(x) = -f(x)$, we reflect $y = f(x)$ in the x -axis. To do this we keep the x -coordinates the same and take the negative of the y -coordinates.

iii The point transformed to $(-3, -2)$ is $(-3, 2)$.

6 a To transform $y = f(x)$ to $h(x) = f(-x)$, we reflect $y = f(x)$ in the y -axis. To do this we keep the y -coordinates the same and take the negative of the x -coordinates.

i $(2, -1)$ is transformed to $(-2, -1)$.

ii $(0, 3)$ is transformed to $(0, 3)$.

iii $(-1, 2)$ is transformed to $(1, 2)$.

b To find the points on $f(x)$ corresponding to $h(x)$, we again take the negative of the x -coordinates.

i The point transformed to $(5, -4)$ is $(-5, -4)$.

ii The point transformed to $(0, 3)$ is $(0, 3)$.

iii The point transformed to $(2, 3)$ is $(-2, 3)$.

iv The point transformed to $(3, 0)$ is $(-3, 0)$.

7 a To transform $y = f(x)$ to $m(x) = f^{-1}(x)$, we reflect $y = f(x)$ in the line $y = x$. To do this we swap the x and y -coordinates.

i $(3, 1)$ is transformed to $(1, 3)$.

ii $(-2, 4)$ is transformed to $(4, -2)$.

iii $(0, -5)$ is transformed to $(-5, 0)$.

-

- ii The reflection of $y = f(x)$ in the line $y = x$ is not $y = f^{-1}(x)$ as $y = f(x)$ is not a function.

 - a Under a vertical stretch with scale factor $\frac{1}{2}$, $y = \frac{1}{x}$ becomes $y = \frac{1}{2} \left(\frac{1}{x} \right)$. $\therefore y = \frac{1}{2x}$
 - b Under a horizontal stretch with scale factor 3, $y = \frac{1}{x}$ becomes $y = \frac{1}{\left(\frac{x}{3} \right)}$. $\therefore y = \frac{3}{x}$
 - c Under a horizontal translation of -3 , $y = \frac{1}{x}$ becomes $y = \frac{1}{x+3}$.
 - d Under a vertical translation of 4, $y = \frac{1}{x}$ becomes $y = \frac{1}{x} + 4$. $\therefore y = \frac{4x+1}{x}$
- 2
 - a Under a vertical stretch with scale factor 3, $f(x)$ becomes $3f(x)$.
 $\therefore \frac{1}{x}$ becomes $3 \left(\frac{1}{x} \right) = \frac{3}{x}$.
 Under a translation of $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$, $f(x)$ becomes $f(x-1) - 1$.
 $\therefore \frac{3}{x}$ becomes $\frac{3}{x-1} - 1$.
 So, $y = \frac{1}{x}$ becomes $g(x) = \frac{3}{x-1} - 1$

$$= \frac{3 - (x-1)}{x-1}$$

$$= \frac{-x+4}{x-1}$$
 - b The asymptotes of $y = \frac{1}{x}$ are $x = 0$ and $y = 0$.
 These are unchanged by the stretch, and shifted $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$ by the translation.
 $\therefore$ the vertical asymptote is $x = 1$ and the horizontal asymptote is $y = -1$.
 - c Domain is $\{x \mid x \neq 1\}$, range is $\{y \mid y \neq -1\}$.

- e** The graph is not symmetric about $y = x$,
so $g(x)$ is not a self-inverse function.

3 a i $f(x) = \frac{2x+4}{x-1}$

$$= \frac{2(x-1)+6}{x-1}$$

$$= \frac{6}{x-1} + 2$$

$y = f(x)$ is a translation of $y = \frac{6}{x}$ through $\begin{pmatrix} 1 \\ 2 \end{pmatrix}$.

Now $y = \frac{6}{x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = 1$ and horizontal asymptote $y = 2$.

ii $\frac{1}{x}$ becomes $\frac{6}{x}$ under a vertical stretch with scale factor 6.

$\frac{6}{x}$ becomes $\frac{6}{x-1} + 2$ under a translation through $\begin{pmatrix} 1 \\ 2 \end{pmatrix}$.

So, $y = \frac{1}{x}$ is transformed to $y = f(x)$ under a vertical stretch with scale factor 6, followed by a translation through $\begin{pmatrix} 1 \\ 2 \end{pmatrix}$.

b i $f(x) = \frac{3x-2}{x+1}$

$$= \frac{3(x+1)-5}{x+1}$$

$$= -\frac{5}{x+1} + 3$$

$y = f(x)$ is a translation of $y = -\frac{5}{x}$ through $\begin{pmatrix} -1 \\ 3 \end{pmatrix}$.

Now $y = -\frac{5}{x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = -1$ and horizontal asymptote $y = 3$.

ii $\frac{1}{x}$ becomes $\frac{5}{x}$ under a vertical stretch with scale factor 5.

$\frac{5}{x}$ becomes $-\frac{5}{x}$ under a reflection in the x -axis.

$-\frac{5}{x}$ becomes $-\frac{5}{x+1} + 3$ under a translation through $\begin{pmatrix} -1 \\ 3 \end{pmatrix}$.

So, $y = \frac{1}{x}$ is transformed to $y = f(x)$ under a vertical stretch with scale factor 5, followed by a reflection in the x -axis, followed by a translation through $\begin{pmatrix} -1 \\ 3 \end{pmatrix}$.

c i $f(x) = \frac{2x+1}{2-x}$

$$= \frac{-2(2-x)+5}{2-x}$$

$$= \frac{5}{2-x} - 2$$

$$= -\frac{5}{x-2} - 2$$

$y = f(x)$ is a translation of $y = -\frac{5}{x}$ through $\begin{pmatrix} 2 \\ -2 \end{pmatrix}$.

Now $y = -\frac{5}{x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = 2$ and horizontal asymptote $y = -2$.

ii $\frac{1}{x}$ becomes $\frac{5}{x}$ under a vertical stretch with scale factor 5.

$\frac{5}{x}$ becomes $-\frac{5}{x}$ under a reflection in the x -axis.

$-\frac{5}{x}$ becomes $-\frac{5}{x-2} - 2$ under a translation through $\begin{pmatrix} 2 \\ -2 \end{pmatrix}$.

So, $y = \frac{1}{x}$ is transformed to $y = f(x)$ under a vertical stretch with scale factor 5, followed by a reflection in the x -axis, followed by a translation through $\begin{pmatrix} 2 \\ -2 \end{pmatrix}$.

$y = f(x)$ is a translation of $y = \frac{1}{x}$ through $\begin{pmatrix} -1 \\ 2 \end{pmatrix}$.

Now $y = \frac{1}{x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = -1$ and horizontal asymptote $y = 2$.

ii As $x \rightarrow -1^-$, $y \rightarrow -\infty$.

As $x \rightarrow -1^+$, $y \rightarrow \infty$.

As $x \rightarrow -\infty$, $y \rightarrow 2^-$.

As $x \rightarrow \infty$, $y \rightarrow 2^+$.

iii When $x = 0$, $y = \frac{1}{1} + 2 = 3$.
 $\therefore$ the y -intercept is 3.

When $y = 0$, $2x + 3 = 0$
 $\therefore x = -\frac{3}{2}$
 $\therefore$ the x -intercept is $-\frac{3}{2}$.

v $\frac{1}{x}$ becomes $\frac{1}{x+1} + 2$ under a translation through $\begin{pmatrix} -1 \\ 2 \end{pmatrix}$.

So, $y = \frac{1}{x}$ is transformed to $y = f(x)$ under a translation through $\begin{pmatrix} -1 \\ 2 \end{pmatrix}$.

vi To transform $y = f(x)$ into $y = \frac{1}{x}$, we need to reverse the process in v.
 We need a translation through $\begin{pmatrix} 1 \\ -2 \end{pmatrix}$.

$$\text{b i } f(x) = \frac{3}{x-2}$$

$y = f(x)$ is a translation of $y = \frac{3}{x}$ through $\begin{pmatrix} 2 \\ 0 \end{pmatrix}$.

Now $y = \frac{3}{x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = 2$ and horizontal asymptote $y = 0$.

As $x \rightarrow 2^+$, $y \rightarrow \infty$.

As $x \rightarrow -\infty$, $y \rightarrow 0^-$.

As $x \rightarrow \infty$, $y \rightarrow 0^+$.

iii When $x = 0$, $y = \frac{3}{-2} = -1\frac{1}{2}$.
 $\therefore$ the y -intercept is $-1\frac{1}{2}$.

When $y = 0$, $\frac{3}{x-2} = 0$

which is not possible

$\therefore$ no x -intercept.

v $\frac{1}{x}$ becomes $\frac{3}{x}$ under a vertical stretch with scale factor 3.

$\frac{3}{x}$ becomes $\frac{3}{x-2}$ under a translation through $\begin{pmatrix} 2 \\ 0 \end{pmatrix}$.

So, $y = \frac{1}{x}$ is transformed to $y = f(x)$ under a vertical stretch with scale factor 3, followed by a translation through $\begin{pmatrix} 2 \\ 0 \end{pmatrix}$.

vi To transform $y = f(x)$ into $y = \frac{1}{x}$, we need to reverse the process in v.

We need a translation through $\begin{pmatrix} -2 \\ 0 \end{pmatrix}$, followed by a vertical stretch with scale factor $\frac{1}{3}$.

 \end{aligned}$$

$y = f(x)$ is a translation of $y = -\frac{5}{x}$ through $\begin{pmatrix} 3 \\ -2 \end{pmatrix}$.

Now $y = -\frac{5}{x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = 3$ and horizontal asymptote $y = -2$.

 As $x \rightarrow 3^+$, $y \rightarrow -\infty$.
 As $x \rightarrow -\infty$, $y \rightarrow -2^+$.
 As $x \rightarrow \infty$, $y \rightarrow -2^-$.

iii When $x = 0$, $y = \frac{-5}{-3} - 2 = -\frac{1}{3}$.

$\therefore$ the y -intercept is $-\frac{1}{3}$.

When $y = 0$, $2x - 1 = 0$
 $\therefore x = \frac{1}{2}$

$\therefore$ the x -intercept is $\frac{1}{2}$.

v $\frac{1}{x}$ becomes $\frac{5}{x}$ under a vertical stretch with scale factor 5.

$\frac{5}{x}$ becomes $-\frac{5}{x}$ under a reflection in the x -axis.

$-\frac{5}{x}$ becomes $-\frac{5}{x-3} - 2$ under a translation through $\begin{pmatrix} 3 \\ -2 \end{pmatrix}$.

So, $y = \frac{1}{x}$ is transformed to $y = f(x)$ under a vertical stretch with scale factor 5, followed by a reflection in the x -axis, followed by a translation through $\begin{pmatrix} 3 \\ -2 \end{pmatrix}$.

vi To transform $y = f(x)$ into $y = \frac{1}{x}$, we need to reverse the process in v.

$y = f(x)$ is a translation of $y = -\frac{7}{4x}$ through $\begin{pmatrix} -\frac{1}{2} \\ \frac{5}{2} \end{pmatrix}$.

Now $y = -\frac{7}{4x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = -\frac{1}{2}$ and horizontal asymptote $y = 2\frac{1}{2}$.

 As $x \rightarrow \infty$, $y \rightarrow 2\frac{1}{2}^-$.

iii When $x = 0$, $y = \frac{-1}{1} = -1$.

$\therefore$ the y -intercept is -1 .

When $y = 0$, $5x - 1 = 0$
 $\therefore x = \frac{1}{5}$

$\therefore$ the x -intercept is $\frac{1}{5}$.

v $\frac{1}{x}$ becomes $\frac{\frac{7}{4}}{x}$ under a vertical stretch with scale factor $\frac{7}{4}$.

- iii For $y = 2^x$, domain is $\{x \mid x \in \mathbb{R}\}$,
range is $\{y \mid y > 0\}$.
- For $y = 2^{x-1} - 2$, domain is $\{x \mid x \in \mathbb{R}\}$,
range is $\{y \mid y > -2\}$.

- a $f(x) = x + 2$
stretching $f(x)$ vertically with scale factor 2 becomes $2f(x) = 2x + 4$
stretching the function horizontally with scale factor $\frac{1}{2}$ becomes $2f(2x) = 2(2x) + 4 = 4x + 4$
translating $\frac{1}{2}$ horizontally and -3 vertically, the function becomes $4(x - \frac{1}{2}) + 4 - 3 = 4x - 2 + 1 = 4x - 1$
 $\therefore F(x) = 4x - 1$
- b $(1, 3) \rightarrow (1, 6) \rightarrow (\frac{1}{2}, 6) \rightarrow (1, 6) \rightarrow (1, 3)$
 $\therefore (1, 3)$ is an invariant point under the transformation.
- c $(0, 2) \rightarrow (0, 4) \rightarrow (0, 4) \rightarrow (\frac{1}{2}, 4) \rightarrow (\frac{1}{2}, 1) \therefore (0, 2)$ transforms to $(\frac{1}{2}, 1)$.
 $(-1, 1) \rightarrow (-1, 2) \rightarrow (-\frac{1}{2}, 2) \rightarrow (0, 2) \rightarrow (0, -1) \therefore (-1, 1)$ transforms to $(0, -1)$.
- d When $x = \frac{1}{2}$, $F(x) = 4(\frac{1}{2}) - 1 = 1 \therefore (\frac{1}{2}, 1)$ lies on $F(x)$.
When $x = 0$, $F(x) = 4(0) - 1 = -1 \therefore (0, -1)$ lies on $F(x)$.

9

10 a $f(x) = \frac{2x-3}{3x+5}$

$$= \frac{\frac{2}{3}x - 1}{x + \frac{5}{3}}$$

$$= \frac{\frac{2}{3}(x + \frac{5}{3}) - \frac{19}{9}}{x + \frac{5}{3}}$$

$$= -\frac{\frac{19}{9}}{x + \frac{5}{3}} + \frac{2}{3}$$

$y = f(x)$ is a translation of $y = -\frac{19}{9x}$ through $\begin{pmatrix} -\frac{5}{3} \\ \frac{2}{3} \end{pmatrix}$.

Now $y = -\frac{19}{9x}$ has asymptotes $x = 0$ and $y = 0$.

$\therefore y = f(x)$ has vertical asymptote $x = -\frac{5}{3}$ and horizontal asymptote $y = \frac{2}{3}$.

- b** As $x \rightarrow -\frac{5}{3}^-$, $y \rightarrow \infty$.
 As $x \rightarrow -\frac{5}{3}^+$, $y \rightarrow -\infty$.
 As $x \rightarrow -\infty$, $y \rightarrow \frac{2}{3}^+$.
 As $x \rightarrow \infty$, $y \rightarrow \frac{2}{3}^-$.

- c** When $x = 0$, $y = -\frac{3}{5}$.
 $\therefore$ the y -intercept is $-\frac{3}{5}$.
 When $y = 0$, $2x - 3 = 0$
 $\therefore x = \frac{3}{2}$
 $\therefore$ the x -intercept is $\frac{3}{2}$.

- e** $\frac{1}{x}$ becomes $\frac{19}{9x}$ under a vertical stretch with scale factor $\frac{19}{9}$.
 $\frac{19}{9x}$ becomes $-\frac{19}{9x}$ under a reflection in the x -axis.
 $-\frac{19}{9x}$ becomes $-\frac{19}{9(x + \frac{5}{3})} + \frac{2}{3}$ under a translation through $\begin{pmatrix} -\frac{5}{3} \\ \frac{2}{3} \end{pmatrix}$.
 So, $y = \frac{1}{x}$ is transformed to $y = f(x)$ under a vertical stretch with scale factor $\frac{19}{9}$, followed by a reflection in the x -axis, followed by a translation through $\begin{pmatrix} -\frac{5}{3} \\ \frac{2}{3} \end{pmatrix}$.
- f** To transform $y = f(x)$ into $y = \frac{1}{x}$, we need to reverse the process in **v**.
 We need a translation through $\begin{pmatrix} \frac{5}{3} \\ -\frac{2}{3} \end{pmatrix}$, followed by a reflection in the x -axis, followed by a vertical stretch with scale factor $\frac{9}{19}$.

$f(0) = -2(0) + 3 = 3 \therefore$ the y -intercept of $f(x)$ is 3
 $f(x) = 0$ when $-2x + 3 = 0$
 $\therefore x = \frac{3}{2}$
 $\therefore$ the x -intercept of $f(x)$ is $\frac{3}{2}$.

- b** The invariant points for $y = \frac{1}{f(x)}$ occur when $f(x) = \pm 1$
- $f(x) = 1$ when $-2x + 3 = 1$
 $\therefore 2x = 2$
 $\therefore x = 1$
- $f(x) = -1$ when $-2x + 3 = -1$
 $\therefore 2x = 4$
 $\therefore x = 2$
- $\therefore$ the invariant points are $(1, 1)$ and $(2, -1)$.

c $\frac{1}{f(x)}$ is undefined when $f(x) = 0$
 $\therefore$ the vertical asymptote of $y = \frac{1}{f(x)}$ is $x = \frac{3}{2}$
The y -intercept of $y = \frac{1}{f(x)}$ is $\frac{1}{f(0)} = \frac{1}{3}$

- i** The coordinates of the turning point are $(-2, 1.8)$.
- ii** The equation of the vertical asymptote is $x = 0$.
- iii** The equation of the horizontal asymptote is $y = 2$.
- iv** The x -intercepts are -3.2 and -0.75 .

The coordinates of the points of intersection are $(-3.65, -2.65)$, $(-0.8, 0.2)$, and $(1.55, 2.55)$.

3 So that you can see the answers more easily, they have been drawn on two graphs.

- b** $g(x)$ is obtained from $f(x)$ by a translation of $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ and then a reflection in the x -axis. So, to get the turning point coordinates we add 1 to the x -coordinate and find the negative of the y -coordinate.
 $(1, 4) \mapsto (2, -4)$ and $(3, 0) \mapsto (4, 0)$.
 So, the turning points of $g(x)$ are $(2, -4)$ and $(4, 0)$.

- 5** $f(x) = x^2$ is first reflected in the x -axis to become $-f(x) = -x^2$
 The function is then translated by $\begin{pmatrix} -3 \\ 2 \end{pmatrix}$ to become
 $-f(x+3) + 2 = -(x+3)^2 + 2$
 $\quad \quad \quad = -(x^2 + 6x + 9) + 2$
 $\therefore g(x) = -x^2 - 6x - 7$

- 7** $f(x) = x^3 + 3x^2 - x + 4$
 $g(x) = f(x+1) + 3$
 $\quad \quad \quad = [(x+1)^3 + 3(x+1)^2 - (x+1) + 4] + 3$
 $\quad \quad \quad = x^3 + 3x^2 + 3x + 1 + 3(x^2 + 2x + 1) - x - 1 + 4 + 3$
 $\quad \quad \quad = x^3 + 3x^2 + 3x + 1 + 3x^2 + 6x + 3 - x - 1 + 4 + 3$
 $\quad \quad \quad = x^3 + 6x^2 + 8x + 10$

- 8 a** $f(x) = 3x + 2$
i A translation of 2 units to the left gives $y = f(x+2)$
 $\quad \quad \quad = 3(x+2) + 2$
 $\quad \quad \quad = 3x + 8$
ii A translation of 6 units upwards gives $y = f(x) + 6$
 $\quad \quad \quad = 3x + 2 + 6$
 $\quad \quad \quad = 3x + 8$

- b** $f(x) = ax + b$ translated k units to the left gives
 $y = f(x+k)$
 $\quad \quad \quad = a(x+k) + b$
 $\quad \quad \quad = ax + ak + b$
 $\quad \quad \quad = (ax + b) + ka$
 $\quad \quad \quad = f(x) + ka$
 which is $f(x)$ translated ka units upwards.

- 9 a** $y = \frac{1}{x}$ under a reflection in the y -axis becomes $y = \frac{1}{(-x)} = -\frac{1}{x}$
 $y = -\frac{1}{x}$ under a vertical stretch with scale factor 3 becomes $y = 3\left(-\frac{1}{x}\right) = -\frac{3}{x}$
 $y = -\frac{3}{x}$ under a translation of $\begin{pmatrix} 1 \\ 1 \end{pmatrix}$ becomes $y = \frac{-3}{x-1} + 1$

- c** Yes, since it is a one-to-one function (passes both the vertical and horizontal line tests).

d $f(x) = y = \frac{-3}{x-1} + 1$

$\therefore$ inverse function is $x = \frac{-3}{y-1} + 1$

$\therefore x - 1 = \frac{-3}{y-1}$

$\therefore y - 1 = \frac{-3}{x-1}$

$\therefore y = \frac{-3}{x-1} + 1$

$\therefore f^{-1}(x) = f(x) = \frac{-3}{x-1} + 1$

$\therefore$ it is a self-inverse function.

Also, the graph of $f(x)$ is symmetrical about the line $y = x$.

- 10 a** Under translation $\begin{pmatrix} 1 \\ -2 \end{pmatrix}$,

$$y = \log_4 x$$

becomes $y = \log_4(x-1) - 2$

- c** For $y = \log_4 x$, VA is $x = 0$, no HA.
For $y = \log_4(x-1) - 2$, VA is $x = 1$, no HA.

- d** For $y = \log_4 x$,
domain is $\{x \mid x > 0\}$,
range is $\{y \mid y \in \mathbb{R}\}$.
- For $y = \log_4(x-1) - 2$,
domain is $\{x \mid x > 1\}$,
range is $\{y \mid y \in \mathbb{R}\}$.

- 11 a** Under a vertical stretch with scale factor $\frac{1}{3}$, $f(x)$ becomes $\frac{1}{3}f(x)$.

$\therefore \frac{1}{x}$ becomes $\frac{1}{3} \left(\frac{1}{x} \right) = \frac{1}{3x}$

Under a reflection in the y -axis, $f(x)$ becomes $f(-x)$.

$\therefore \frac{1}{3x}$ becomes $\frac{1}{3(-x)} = \frac{-1}{3x}$

Under a translation of 2 units to the right, $f(x)$ becomes $f(x-2)$.

$\therefore \frac{-1}{3x}$ becomes $\frac{-1}{3(x-2)} = \frac{-1}{3x-6}$

So, $y = \frac{1}{x}$ becomes $g(x) = \frac{-1}{3x-6}$.

- b** The asymptotes of $y = \frac{1}{x}$ are $x = 0$ and $y = 0$.

These are unchanged by the stretch and the reflection, and shifted 2 units to the right by the translation.

$\therefore$ the vertical asymptote is $x = 2$ and the horizontal asymptote is $y = 0$.

- c** Domain is $\{x \mid x \neq 2\}$,
range is $\{y \mid y \neq 0\}$.

EXERCISE 6D.2

1

a

$2x^2 + 4x + 5 = ax^2 + (2b - 6)x + c$
Equating coefficients gives
 $a = 2, 2b - 6 = 4, \text{ and } c = 5$

$\therefore 2b = 10$
 $\therefore b = 5$
 $\therefore a = 2, b = 5, c = 5$

b

$2x^3 - x^2 + 6 = (x - 1)^2(2x + a) + bx + c$
 $= (x^2 - 2x + 1)(2x + a) + bx + c$
 $= 2x^3 + (a - 4)x^2 + (2 - 2a)x + a + bx + c$
 $= 2x^3 + (a - 4)x^2 + (2 - 2a + b)x + (a + c)$
Equating coefficients gives $a - 4 = -1$ $2 - 2a + b = 0$ $a + c = 6$
 $\therefore a = 3$ $\therefore b = 2a - 2$ $\therefore c = 6 - a$
 $\therefore b = 4$ $\therefore c = 3$

a

$z^4 + 4 = (z^2 + az + 2)(z^2 + bz + 2)$
 $= z^4 + (a + b)z^3 + (4 + ab)z^2 + (2a + 2b)z + 4$
Equating coefficients gives: $a + b = 0$ $4 + ab = 0$
 $\therefore a = -b$ $\therefore ab = -4$
By inspection $a = 2$ and $b = -2$
or $a = -2$ and $b = 2$

$$\begin{aligned} \mathbf{b} \quad & 2z^4 + 5z^3 + 4z^2 + 7z + 6 \\ &= (z^2 + az + 2)(2z^2 + bz + 3) \\ &= 2z^4 + (2a + b)z^3 + (ab + 7)z^2 + (3a + 2b)z + 6 \end{aligned}$$

$$\begin{aligned} \text{Equating coefficients gives: } & 2a + b = 5 \quad \dots (1) \\ & 3a + 2b = 7 \quad \dots (2) \\ & ab + 7 = 4 \quad \dots (3) \\ \therefore & 4a + 2b = 10 \quad \{(1) \times 2\} \\ \text{and } & 3a + 2b = 7 \end{aligned}$$

and solving these two equations gives $a = 3$, $b = -1$
which checks with (3) as $ab + 7 = -3 + 7 = 4 \quad \checkmark$

$$\begin{array}{r} \begin{array}{rrr} & 1 & a & 2 \\ & \times & 2 & b & 3 \\ \hline & & 3 & 3a & 6 \\ & b & ab & 2b \\ 2 & 2a & 4 & & \\ \hline 2 & 2a + b & ab + 7 & 3a + 2b & 6 \end{array} \end{array}$$

3 Consider

$$\begin{aligned} & z^4 + 64 \\ &= (z^2 + az + 8)(z^2 + bz + 8) \\ &= z^4 + (a + b)z^3 + (ab + 16)z^2 + (8a + 8b)z + 64 \end{aligned}$$

Equating coefficients gives:

$$\begin{aligned} a + b &= 0 \quad \text{and} \quad ab + 16 = 0 \\ \therefore a &= -b \quad \therefore ab = -16 \end{aligned}$$

$$\begin{aligned} \therefore \text{by inspection } a &= 4 \quad \text{and} \quad b = -4 \\ \text{or } a &= -4 \quad \text{and} \quad b = 4 \end{aligned}$$

$$\therefore z^4 + 64 \text{ can be factorised into } (z^2 + 4z + 8)(z^2 - 4z + 8)$$

Now consider

$$\begin{aligned} & z^4 + 64 \\ &= (z^2 + az + 16)(z^2 + bz + 4) \\ &= z^4 + (a + b)z^3 + (ab + 20)z^2 + (4a + 16b)z + 64 \end{aligned}$$

Equating coefficients gives:

$$\begin{aligned} a + b &= 0 \quad \dots (1) \quad \text{and} \quad ab + 20 = 0 \\ 4a + 16b &= 0 \quad \dots (2) \quad \therefore ab = -20 \quad \dots (3) \end{aligned}$$

Solution to (1), (2) is $a = b = 0$

But this does not satisfy (3)

$\therefore$ no values of a and b exist which obey the original assumption

$\therefore$ cannot be factorised in this way.

$$\begin{array}{r} \begin{array}{rrr} & 1 & a & 8 \\ & \times & 1 & b & 8 \\ \hline & & 8 & 8a & 64 \\ & b & ab & 8b \\ 1 & a & 8 & & \\ \hline 1 & a + b & ab + 16 & 8a + 8b & 64 \end{array} \end{array}$$

4 Consider

$$\begin{aligned} & x^4 - 4x^2 + 8x - 4 \\ &= (x^2 + ax + 2)(x^2 + bx - 2) \\ &= x^4 + (a + b)x^3 + (ab)x^2 + (2b - 2a)x - 4 \end{aligned}$$

Equating coefficients gives:

$$\begin{aligned} a + b &= 0 \quad \text{and} \quad ab = -4 \quad \text{and} \quad -2a + 2b = 8 \\ \therefore 2a + 2b &= 0 \quad \dots (1) \\ -2a + 2b &= 8 \quad \dots (2) \end{aligned}$$

Adding (1) and (2) gives $4b = 8 \quad \therefore b = 2$ and hence $a = -2$, which checks with $ab = -4 \quad \checkmark$

$$\therefore P(x) = (x^2 - 2x + 2)(x^2 + 2x - 2)$$

$$\text{Now if } x^4 + 8x = 4x^2 + 4$$

$$\text{then } x^4 - 4x^2 + 8x - 4 = 0$$

$$\therefore (x^2 - 2x + 2)(x^2 + 2x - 2) = 0$$

$$\therefore x^2 - 2x + 2 = 0 \quad \text{or} \quad x^2 + 2x - 2 = 0$$

$$\therefore x = \frac{2 \pm \sqrt{4 - 8}}{2} = 1 \pm i \quad \text{or} \quad x = \frac{-2 \pm \sqrt{4 + 8}}{2} = -1 \pm \sqrt{3}$$

$$\therefore x = 1 \pm i, -1 \pm \sqrt{3}$$

 $2b = 2$ $\therefore a = 2 - 3$
 $b = 1$ $a = -1$

$\therefore P(z) = (2z - 3)(z^2 + z + 1)$
this quadratic has zeros $z = \frac{-1 \pm \sqrt{1 - 4}}{2} = \frac{-1 \pm i\sqrt{3}}{2}$

Equating coefficients gives:

$\therefore 2 + 3b = -1, 2b + 3c = a + 1,$ and $2c = a$
Now as $2 + 3b = -1$
 $\therefore 3b = -3$
 $\therefore b = -1$

Substituting $b = -1$ and $a = 2c$ into $2b + 3c = a + 1$ gives $2(-1) + 3c = 2c + 1$
 $\therefore -2 + 3c = 2c + 1$
 $c = 3$
and so $a = 6$

Equating coefficients: $2c - 3 = a,$
 $6 - 3c = b,$ and $-2c - 12 = -12$
The last equation has solution $c = 0,$ and

 &= (x^2 + 2ax + a^2)(x + b) \\
 &= x^3 + (b + 2a)x^2 + (a^2 + 2ab)x + a^2b
 \end{aligned}$$

Equating coefficients gives

$$2a + b = 3, \quad a^2 + 2ab = -9, \quad \text{and} \quad c = a^2b$$

Substituting $b = 3 - 2a$ into the second equation gives:

$$\begin{aligned}
 &a^2 + 2a(3 - 2a) = -9 \\
 \therefore a^2 + 6a - 4a^2 &= -9 \\
 \therefore -3a^2 + 6a &= -9 \\
 \therefore 3a^2 - 6a - 9 &= 0 \\
 \therefore a^2 - 2a - 3 &= 0 \\
 \therefore (a - 3)(a + 1) &= 0
 \end{aligned}$$

$$\therefore \begin{cases} a = 3 \\ b = -3 \\ c = -27 \end{cases} \quad \text{or} \quad \begin{cases} a = -1 \\ b = 5 \\ c = 5 \end{cases}$$

 &= 3x^3 + (6a + b)x^2 + (3a^2 + 2ab)x + a^2b
 \end{aligned}$$

Equating coefficients gives

$$6a + b = 4, \quad 3a^2 + 2ab = -1, \quad \text{and} \quad a^2b = m$$

Substituting $b = 4 - 6a$ into the second equation gives:

$$\begin{aligned}
 &3a^2 + 2a(4 - 6a) = -1 \\
 \therefore 3a^2 + 8a - 12a^2 &= -1 \\
 \therefore 9a^2 - 8a - 1 &= 0 \\
 \therefore (9a + 1)(a - 1) &= 0 \\
 \therefore a &= -\frac{1}{9} \text{ or } a = 1
 \end{aligned}$$

When $a = 1$, $b = -2$ and $m = -2$. So, $P(x) = (x + 1)^2(3x - 2)$ $\therefore$ zeros are $-1, \frac{2}{3}$

When $a = -\frac{1}{9}$, $b = \frac{14}{3}$ and $m = \frac{14}{243}$. So, $P(x) = (x - \frac{1}{9})^2(3x + \frac{14}{3})$

$\therefore$ zeros are $\frac{1}{9}, -\frac{14}{9}$

EXERCISE 6E.1

- 1 a** If $P(2) = 7$, then $P(x) = Q(x)(x - 2) + 7$ and $P(x)$ divided by $(x - 2)$ leaves a remainder of 7.
 - b** If $P(x) = Q(x)(x + 3) - 8$, then $P(-3) = -8$ and $P(x)$ divided by $(x + 3)$ leaves a remainder of -8 .
 - c** If $P(x)$ when divided by $(x - 5)$ has a remainder of 11, then $P(5) = 11$ and $P(x) = Q(x)(x - 5) + 11$.
- 2 a** $P(x) = x^3 + 2x^2 - 7x + 5$
 $\therefore R = P(1)$ {Remainder theorem}
 $= 1^3 + 2(1)^2 - 7 + 5$
 $= 1$
 - b** $P(x) = x^4 - 2x^2 + 3x - 1$
 $\therefore R = P(-2)$ {Remainder theorem}
 $= (-2)^4 - 2(-2)^2 + 3(-2) - 1$
 $= 16 - 8 - 6 - 1$
 $= 1$

3 a $P(x) = x^3 - 2x + a$

Now $P(2) = 7$ {Remainder theorem}

$$\therefore 2^3 - 2(2) + a = 7$$
$$4 + a = 7$$
$$\therefore a = 3$$

b $P(x) = 2x^3 + x^2 + ax - 5$

Now $P(-1) = -8$

$$\therefore 2(-1)^3 + (-1)^2 + a(-1) - 5 = -8$$
$$-2 + 1 - a - 5 = -8$$
$$\therefore -a - 6 = -8$$
$$-a = -2$$
$$\therefore a = 2$$

4 $P(x) = x^3 + 2x^2 + ax + b$

Now $P(1) = 4$ and $P(-2) = 16$ {Remainder theorem}

If $P(1) = 4$ then $1 + 2 + a + b = 4$ and so $a + b = 1$ (1)

If $P(-2) = 16$ then $(-2)^3 + 2(-2)^2 + a(-2) + b = 16$

$$\therefore -8 + 8 - 2a + b = 16$$
$$\therefore -2a + b = 16$$
 (2)

Solving (1) and (2)

$$-a - b = -1$$
$$-2a + b = 16$$
$$\therefore -3a = 15$$
 {adding}
$$\therefore a = -5$$
 and so $b = 6$
$$\therefore a = -5$$
 and $b = 6$

5 $P(x) = 2x^n + ax^2 - 6$

By the Remainder theorem, $P(1) = -7$ $\therefore 2(1)^n + a(1)^2 - 6 = -7$

$$\therefore 2 + a - 6 = -7$$
$$\therefore a = -3$$

So, $P(x) = 2x^n - 3x^2 - 6$

and since $P(-3) = 129$, $\therefore 2(-3)^n - 3(-3)^2 - 6 = 129$

$$2(-3)^n - 27 - 6 = 129$$
$$2(-3)^n = 162$$
$$(-3)^n = 81$$
$$\therefore n = 4$$
$$\therefore a = -3$$
 and $n = 4$

6 $P(z) = Q(z)(z^2 - 3z + 2) + (4z - 7) = Q(z)(z - 2)(z - 1) + (4z - 7)$

a Remainder is $P(1)$ {Remainder theorem}

$$\therefore R = Q(1) \times (1 - 2) \times 0 + (4 - 7)$$
$$= -3$$

b Remainder is $P(2)$ {Remainder theorem}

$$\therefore R = Q(2) \times 0 \times (2 - 1) + [4(2) - 7]$$
$$= 0 + 1$$
$$= 1$$

7 Suppose $P(z)$ is divided by $(z - 3)(z + 1)$

$$\therefore P(z) = Q(z) \times (z - 3)(z + 1) + (Az + B)$$

↑

the remainder must be of this form

Now $P(-1) = -8$ $\therefore Q(-1) \times 0 + (-A + B) = -8$

$$\therefore -A + B = -8$$
 (1)

and $P(3) = 4$ $\therefore Q(3) \times 0 + (3A + B) = 4$

$$\therefore 3A + B = 4$$
 (2)

Solving (1) and (2),

$$-A + B = -8$$
$$-3A - B = -4$$

$$-4A = -12$$
$$\therefore A = 3$$

Subtracting (1) from (2), $P(b) - P(a) = Eb - Ea = E(b-a)$

if $(x + 1)$ is a factor then
 $P(-1) = 0$
 $\therefore (-1)^n + 1 = 0$

which is only true if n is odd
 $\therefore (x + 1)$ is a factor of $x^n + 1 \Leftrightarrow n$ is odd.

if n is odd, $(-1)^n = -1$
 $\therefore (-1)^n + 1 = 0$

EXERCISE 6E.3

- 1** Since it is a real polynomial, the zeros must be $-\frac{1}{2}$, $1 - 3i$, and $1 + 3i$.
For $1 \pm 3i$, $\alpha + \beta = 2$, and $\alpha\beta = 1 - 9i^2 = 10$
 $\therefore$ factors are $(2x + 1)$ and $(x^2 - 2x + 10)$
 $\therefore P(x) = a(2x + 1)(x^2 - 2x + 10)$, $a \neq 0$

2 $p(1) = p(2 + i) = 0$

Hence zeros of $p(x)$ must be $1, 2 \pm i$ {as $p(x)$ is real}

For $2 \pm i$, $\alpha + \beta = 4$ and $\alpha\beta = 4 - i^2 = 5$

$\therefore$ factors must be $(x - 1)$ and $(x^2 - 4x + 5)$

$\therefore p(x) = k(x - 1)(x^2 - 4x + 5)$

Since $p(0) = -20$ then $-20 = k(-1)(5)$

$\therefore k = 4$

$\therefore p(x) = 4(x - 1)(x^2 - 4x + 5)$

$\therefore p(x) = 4x^3 - 20x^2 + 36x - 20$

3 a $2 - 3i$ is a zero of $z^3 + pz + q$ and as the cubic has real coefficients, $2 + 3i$ is also a zero.

For $2 \pm 3i$, $\alpha + \beta = 4$ and $\alpha\beta = 4 - 9i^2 = 13$

$\therefore z^2 - 4z + 13$ is a factor

$\therefore z^3 + pz + q = (z^2 - 4z + 13)(z + a)$ for some a
 $= z^3 + (a - 4)z^2 + (13 - 4a)z + 13a$

Equating coefficients:

$a - 4 = 0, \quad 13 - 4a = p, \quad \text{and} \quad 13a = q$

$\therefore a = 4, \quad p = -3, \quad q = 52$

$\therefore$ the other zeros are -4 and $2 + 3i$

$$\begin{array}{r} 1 \quad -4 \quad 13 \\ \times \quad 1 \quad a \\ \hline a \quad -4a \quad 13a \\ 1 \quad -4 \quad 13 \\ \hline 1 \quad a - 4 \quad 13 - 4a \quad 13a \end{array}$$

b Check: Since $P(2 - 3i) = 0$, $(2 - 3i)^3 + p(2 - 3i) + q = 0$

Expanding, $(-46 - 9i) + p(2 - 3i) + q = 0$

$\therefore (-46 + 2p + q) + (-9 - 3p)i = 0$

Equating real and imaginary parts, $-46 + 2p + q = 0 \dots (1)$

and $-9 - 3p = 0 \dots (2)$

From (2), $p = -3$, so in (1), $-46 - 6 + q = 0 \therefore p = -3, q = 52 \checkmark$

4 $3 + i$ is a root of $z^4 - 2z^3 + az^2 + bz + 10 = 0$ where the coefficients are real.

$\therefore 3 - i$ is also a root

For $3 \pm i$, $\alpha + \beta = 6$ and $\alpha\beta = 9 - i^2 = 10$

$\therefore z^2 - 6z + 10$ is a factor

$\therefore z^4 - 2z^3 + az^2 + bz + 10$
 $= (z^2 - 6z + 10)(z^2 + sz + 1)$ for some s

Equating coefficients:

$s - 6 = -2, \quad 11 - 6s = a \quad \text{and} \quad 10s - 6 = b$

$\therefore s = 4 \quad a = 11 - 6(4) = -13 \quad b = 10(4) - 6 = 34$

$\therefore$ the other factor is $z^2 + 4z + 1$ which has zeros $\frac{-4 \pm \sqrt{16 - 4}}{2} = -2 \pm \sqrt{3}$

$\therefore a = -13, b = 34$ and the other roots are $3 - i, -2 \pm \sqrt{3}$.

5 Let the purely imaginary zero be bi . Since $P(z)$ is real, another zero is $-bi$ (b is real).

$\therefore z^2 + b^2$ is a factor of $P(z)$

$\therefore z^3 + az^2 + 3z + 9 = (z^2 + b^2)(z + c)$
 $= z^3 + cz^2 + b^2z + b^2c$

Equating coefficients, $b^2 = 3, b^2c = 9$, and $a = c$

$\therefore c = 3, a = 3$, and $b = \pm\sqrt{3}$

$\therefore P(z) = (z + 3)(z^2 + 3)$

$\therefore P(z) = (z + 3)(z + i\sqrt{3})(z - i\sqrt{3}), a = 3$

- 6 Let ai be the purely imaginary zero of $3x^3 + kx^2 + 15x + 10$
 $\therefore$ as $P(x)$ is real, $-ai$ is also a zero

For $\pm ai$, $\alpha + \beta = 0$ and $\alpha\beta = -a^2i^2 = a^2$

$\therefore x^2 + a^2$ is a factor

$$\begin{aligned}\therefore 3x^3 + kx^2 + 15x + 10 &= (x^2 + a^2)(3x + b) \\ &= 3x^3 + bx^2 + 3a^2x + a^2b\end{aligned}$$

Equating coefficients, $k = b$

$$\text{and } 3a^2 = 15 \quad \therefore a^2 = 5$$

$$\text{and } a^2b = 10 \quad \therefore b = 2 \quad \therefore k = 2$$

$$\therefore P(x) = (x^2 + 5)(3x + 2)$$

$$\therefore P(x) = (3x + 2)(x - i\sqrt{5})(x + i\sqrt{5}), \quad k = 2$$

$$\therefore -2(9+1)(k-1) = 18$$

$$\therefore -20(k-1) = 18$$

$$\therefore k-1 = \frac{-9}{10}$$

$$\therefore k = \frac{1}{10}$$

5 a $f(t) = kt(t - a)^2$

From the graph a is the t -value at the point where the graph touches the t -axis.
 $\therefore a = 700$ milliseconds
This represents the time when the barrier has returned to its original position.

b when $t = 100$ ms $f(t) = 85$ mm

$\therefore 85 = k \times 100(100 - 700)^2$
 $85 = 100 \times k \times 360\,000$

$k = \frac{85}{36\,000\,000}$

$\therefore f(t) = \frac{85t}{36\,000\,000}(t - 700)^2$

6 $V(t) = -t^3 + 30t^2 - 131t + 250$

We graph $V(t)$ against t and add the graph of $V(t) = 100$.

From the graph, the level drops below 100 ML when $t = 2$ and rises above 100 ML again when $t = 3$.

Now if $t = 0$ is Jan 1st,

$0 \leq t < 1$ is January.

$\therefore$ as irrigation is prohibited for $2 < t < 3$, it is banned during March.

Let the height of the wall where the ladder touches be x m.

Using similar triangles AXB, AOC:

$$\frac{x-1}{1} = \frac{x}{OC}$$

$$\therefore OC = \frac{x}{x-1}$$

$$\text{but } x^2 + OC^2 = 10^2$$

$$x^2 + \left(\frac{x}{x-1}\right)^2 = 100$$

Using technology to find the intersection of $y = x^2 + \left(\frac{x}{x-1}\right)^2$ and $y = 100$

$$x \approx 1.112 \text{ or } 9.938$$

So, distance ≈ 9.938 m or 1.112 m

10 The Remainder theorem:

“When a polynomial $P(x)$ is divided by $x - k$ until a constant remainder R is obtained then $R = P(k)$.”

Proof: From the division process, $P(x) = (x - k)Q(x) + R$

$$\text{Now, letting } x = k, \quad P(k) = (k - k) \times Q(k) + R$$

$$\therefore P(k) = 0 \times Q(k) + R$$

$$\therefore P(k) = R$$

$$\therefore R = P(k)$$

11 Let $P(z) = z^2 + az + (3 + a)$

if $-2 + bi$ is a zero then

$$P(-2 + bi) = 0$$

$$\therefore (-2 + bi)^2 + a(-2 + bi) + 3 + a = 0$$

$$4 - 4bi + b^2 i^2 - 2a + abi + 3 + a = 0$$

$$(4 - b^2 - 2a + 3 + a) + i(-4b + ab) = 0$$

$$\therefore 4 - b^2 - 2a + 3 + a = 0 \quad \text{and} \quad -4b + ab = 0$$

$$a = 7 - b^2 \quad \therefore b(a - 4) = 0$$

$$\therefore b = 0 \quad \text{or} \quad a = 4$$

If $b = 0$ then $a = 7 - 0 = 7$.

If $a = 4$ then $b^2 = 3$ and so $b = \pm\sqrt{3}$.

12 As $(x - 3)(x + 2) = x^2 - x - 6$,

$P(x) = Q(x)(x^2 - x - 6) + (Ax + B)$, where $Q(x)$ is the quotient and $Ax + B$ is the remainder.

Now $P(x)$ has remainder 2 when divided by $x - 3$ and so $P(3) = 2$ {Remainder theorem}

$$\therefore Q(3)(9 - 3 - 6) + (3A + B) = 2$$

$$\therefore 3A + B = 2 \quad \dots (1)$$

Also $P(x)$ has remainder -13 when divided by $x + 2$ and so $P(-2) = -13$

$$\therefore Q(-2)(4 + 2 - 6) + (-2A + B) = -13$$

$$\therefore -2A + B = -13 \quad \dots (2)$$

Solving (1) and (2): $5A = 15$

$$\therefore A = 3 \quad \text{and} \quad B = -7$$

So, the remainder is $3x - 7$.

13 $2 - i\sqrt{3}$ and $\sqrt{2} + 1$

Since the quartic has real rational coefficients, $2 - i\sqrt{3}$ and $2 + i\sqrt{3}$ are zeros

$\sqrt{2} + 1$ and $-\sqrt{2} + 1$ are zeros

$\therefore$ the four zeros are: $2 \pm i\sqrt{3}$ and $\pm\sqrt{2} + 1$

For $2 \pm i\sqrt{3}$, $\alpha + \beta = 4$

$$\alpha\beta = 4 - 3i^2 = 7$$

$$\therefore P(z) = (z^2 - 4z + 7)(z^2 - 2z - 1)$$

$$\therefore P(z) = z^4 - 6z^3 + 14z^2 - 10z - 7$$

For $\pm\sqrt{2} + 1$, $\alpha + \beta = 2$

$$\alpha\beta = -2 + 1 = -1$$

 $k^2 - 2k(2k - 3) = -9$
 $k^2 - 4k^2 + 6k = -9$
 $\therefore 3k^2 - 6k - 9 = 0$
 $k^2 - 2k - 3 = 0$
 $(k - 3)(k + 1) = 0$
 $\therefore k = -1 \text{ or } k = 3$

If $k = -1$, $a = -5$ and $b = ak^2 = -5$ and so $f(x) = (x + 1)^2(x - 5)$
and the roots of $f(x) = 0$ are $-1, 5$

and the roots of $f(x) = 0$ are $3, -3$

15 Since the coefficients are rational, $3 + i\sqrt{2}$ and $1 + \sqrt{2}$ also have to be zeros.

For zeros of $3 \pm i\sqrt{2}$, $\alpha + \beta = 6$ and $\alpha\beta = 9 - 2i^2 = 11$
For zeros of $1 \pm \sqrt{2}$, $\alpha + \beta = 2$ and $\alpha\beta = 1 - 2 = -1$

 $\alpha\beta + \beta\gamma + \alpha\gamma = -1$
 $\therefore \alpha\beta\gamma = -1$

- 12** Zeros are $2 + i$ and $-1 + 3i$.
Since we have a real polynomial, the other zeros are $2 - i$ and $-1 - 3i$.
For zeros of $2 \pm i$, $\alpha + \beta = 4$ and $\alpha\beta = 4 - i^2 = 5$
For zeros of $-1 \pm 3i$, $\alpha + \beta = -2$ and $\alpha\beta = 1 - 9i^2 = 10$
 $\therefore P(z) = a(z^2 - 4z + 5)(z^2 + 2z + 10), \quad a \neq 0$

- 13** Since $3 - 2i$ is a zero, so is $3 + 2i$. These have $\alpha + \beta = 6$ and $\alpha\beta = 9 - 4i^2 = 13$.

If one zero is purely imaginary, for example, ai , then $-ai$ is also a zero (a is real).

$\pm ai$ have $\alpha + \beta = 0$ and $\alpha\beta = -a^2i^2 = a^2$

$$\mathbf{1} \quad (3x+2yi)(1-i) = (3y+1)i - x$$

$$\therefore 3x - 3xi + 2yi - 2yi^2 = 3yi + i - x$$

$$\therefore (3x+2y) + i(2y-3x) = -x + i(3y+1)$$

Equating real and imaginary parts, $3x+2y = -x$ and $2y-3x = 3y+1$

$$\therefore 4x = -2y \quad \text{and} \quad -1-3x = y$$

$$\therefore 4x = -2(-1-3x)$$

$$\therefore 4x = 2+6x$$

$$= \frac{6-i \pm \sqrt{i^2 - 12i + 36 - 40}}{2}$$

$$= \frac{6-i \pm \sqrt{-5-12i}}{2}$$

We must now find $\sqrt{-5-12i}$

Let $z = a+bi = \sqrt{-5-12i}$, a, b real

$$\therefore (a+bi)^2 = -5-12i$$

$$\therefore a^2 + 2abi + b^2i^2 = -5-12i$$

$$\therefore a^2 - b^2 + 2abi = -5-12i$$

Equating real and imaginary parts,

$$a^2 - b^2 = -5 \quad \text{and} \quad 2ab = -12$$

$$\therefore a^2 - b^2 = -5 \quad \text{and} \quad b = -\frac{6}{a}$$

$$\therefore a^2 - \left(-\frac{6}{a}\right)^2 = -5$$

$$\therefore a^2 - \frac{36}{a^2} = -5$$

$$\therefore a^4 + 5a^2 - 36 = 0$$

$$\therefore (a^2+9)(a^2-4) = 0$$

$$\therefore a = 2 \quad (a \text{ real, } a > 0)$$

$$\text{and } b = \frac{-6}{2} = -3$$

$$\therefore \sqrt{-5-12i} = 2-3i$$

$$\text{so } z = \frac{6-i \pm (2-3i)}{2}$$

Now if $2xy + y = 0$

then $y(2x + 1) = 0$

$$\therefore y = 0 \text{ or } x = -\frac{1}{2}$$

If $y = 0$, then $x^2 = x$ and so $x = 0$ or 1

If $x = -\frac{1}{2}$, then $\frac{1}{4} - y^2 = -\frac{1}{2}$,

$$\therefore y^2 = \frac{3}{4}$$

and so $y = \pm \frac{\sqrt{3}}{2}$

Possible solutions are:

x	0	1	$-\frac{1}{2}$	$-\frac{1}{2}$
y	0	0	$\frac{\sqrt{3}}{2}$	$-\frac{\sqrt{3}}{2}$

5 Let $z = a + bi$ and $w = c + di$ where $b \neq 0$ and $d \neq 0$ (1)

Now $z + w = (a + c) + (b + d)i$ and $zw = (a + bi)(c + di)$
 $= (ac - bd) + i(bc + ad)$

As $z + w$ is real, $b + d = 0 \therefore b = -d$ (2)

As zw is real, $bc + ad = 0$ (3)

Substituting (2) into (3) $-dc + ad = 0$

$$\therefore d(a - c) = 0$$

Since $d \neq 0$ {from (1)}

$$\therefore a = c \text{ and } b = -d$$

$$\therefore z^* = a - bi = c + di = w$$

$$\therefore 4x^4 + (0)x^3 - x^2 - 2x + 6 = 0$$

$$\therefore \text{the sum of the roots is } -\frac{0}{4} = 0$$

Equating coefficients gives $a = b - 20$, $52 - 10b = 62$, and $a - 5 = 26b$.
From $52 - 10b = 62$,
 $-10b = 10$
 $\therefore b = -1$, and since $a = b - 20$ we find $a = -21$.

Check: $a - 5 = -26$ and $26b = -26$ ✓

$\therefore P(z) = 2z^3 - 21z^2 + 62z - 26$

 $\therefore$ other two zeros are $\frac{1}{2}$, $5 + i$, and $a = -21$.

10 a Two zeros are $i\sqrt{2}$ and $\frac{1}{2}$, so another zero must be $-i\sqrt{2}$

	b	$2ab$	a^2b
2	$4a$	$2a^2$	
2	$b + 4a$	$2ab + 2a^2$	a^2b

Equating coefficients gives in (1) and (3):
 $b + 4a = 7$, $2ab + 2a^2 = k$ and $a^2b = -k$
 $\therefore 2ab + 2a^2 = -a^2b$ {equating ks}

Equating coefficients gives: $a = 3c - 8$, $-4a = -8 - 4c$, and $b = -4c$

Equating as gives: $3c - 8 = 2 + c$

$$\therefore 4 - 8k + 4k^2 - 8k^2 + 48k - 72 = 0$$

17

a The polynomial $P(x)$ of degree 5 has zeros $m \pm 2i$, $1 \pm mi$, and 2.

The constant term is the y -intercept. $\therefore$ the constant term is -56 .

$$\therefore \text{the product of the zeros is } 2(m + 2i)(m - 2i)(1 + mi)(1 - mi) = \frac{(-1)^5(-56)}{1}$$

$$\therefore 2(m^2 + 4)(1 + m^2) = 56$$

$$\therefore m^4 + 5m^2 + 4 = 28$$

$$\therefore (m^2)^2 + 5(m^2) - 24 = 0$$

$$\therefore (m^2 + 8)(m^2 - 3) = 0$$

$$\therefore m^2 = -8 \text{ or } m^2 = 3$$

$$\therefore m^2 = 3 \quad \{m^2 \geq 0\}$$

$$\therefore m = \pm\sqrt{3}$$

b Let the coefficient of x^4 be a .

If $m = \sqrt{3}$, then the sum of the zeros is

$$2 + (\sqrt{3} + 2i) + (\sqrt{3} - 2i) + (1 + i\sqrt{3}) + (1 - i\sqrt{3}) = -\frac{a}{1}$$

$$\therefore 2 + 2\sqrt{3} + 2 = -a$$

$$\therefore a = -4 - 2\sqrt{3}$$

If $m = -\sqrt{3}$, then the sum of the zeros is

$$2 + (-\sqrt{3} + 2i) + (-\sqrt{3} - 2i) + (1 - i\sqrt{3}) + (1 + i\sqrt{3}) = -a$$

$$\therefore 2 - 2\sqrt{3} + 2 = -a$$

$$\therefore a = -4 + 2\sqrt{3}$$

So, the coefficient of x^4 is $-4 - 2\sqrt{3}$ if $m = \sqrt{3}$,
and $-4 + 2\sqrt{3}$ if $m = -\sqrt{3}$.

 $t_4 = 15 - (-2)^4 = -1, \quad t_5 = 15 - (-2)^5 = 47$

EXERCISE 7B.2

- 2**
- a** The first term of the sequence is 3. So, $u_1 = 3$.
Each subsequent term is double the previous one. So, $u_n = 2u_{n-1}$.
 $\therefore$ the sequence is defined by $u_1 = 3, u_n = 2u_{n-1}, n > 1$.
- b**
- $u_2 = 2u_1 = 2 \times 3 = 6$
 $u_3 = 2u_2 = 2 \times 6 = 12$

 $u_3 = \frac{1}{1 + u_2} = \frac{1}{1 + \frac{1}{2}} = \frac{1}{\frac{3}{2}} = \frac{2}{3}$
 $u_4 = \frac{1}{1 + u_3} = \frac{1}{1 + \frac{2}{3}} = \frac{1}{\frac{5}{3}} = \frac{3}{5}$
 $u_5 = \frac{1}{1 + u_4} = \frac{1}{1 + \frac{3}{5}} = \frac{1}{\frac{8}{5}} = \frac{5}{8}$

 $\therefore$ as $n \rightarrow \infty, u_n \rightarrow \frac{1}{1 + u}$ and also $u_n \rightarrow u$

$$\therefore u = \frac{1}{1+u}$$

$$\therefore u(1+u) = 1$$

$$\therefore u + u^2 = 1$$

$$\therefore u^2 + u - 1 = 0$$

$$\text{ii } u^2 + u - 1 = 0$$

$$\text{b As } n \rightarrow \infty, u_{n-1} \rightarrow u \text{ and } u_n \rightarrow u$$

$$\therefore \text{ as } n \rightarrow \infty, u_n = \sqrt{\frac{1}{1+u_{n-1}}} \rightarrow \sqrt{\frac{1}{1+u}}$$

$$\text{So, as } n \rightarrow \infty, u_n \rightarrow \sqrt{\frac{1}{1+u}} \text{ and } u_n \rightarrow u$$

$$\therefore u = \sqrt{\frac{1}{1+u}}$$

$$\therefore u^2 = \frac{1}{1+u}$$

$$\therefore u^2(1+u) = 1$$

$$\therefore u^2 + u^3 = 1$$

$$\therefore u^3 + u^2 - 1 = 0$$

- 2** **a** The first term of the arithmetic sequence is 31 and the common difference is $36 - 31 = 5$.

$$u_n = u_1 + (n - 1)d$$

$$\therefore u_n = 31 + 5(n - 1)$$
 So, $u_{15} = 31 + 5(15 - 1)$

$$= 31 + 5 \times 14$$

$$= 101$$
- b** The first term of the arithmetic sequence is 5 and the common difference is $-3 - 5 = -8$.

$$u_n = u_1 + (n - 1)d$$

$$\therefore u_n = 5 + (-8)(n - 1)$$
 So, $u_{15} = 5 + (-8)(15 - 1)$

$$= 5 - 8 \times 14$$

$$= -107$$
- c** The first term of the arithmetic sequence is a and the common difference is $a + d - a = d$.

$$u_n = u_1 + (n - 1)d$$

$$\therefore u_n = a + (n - 1)d$$
 So, $u_{15} = a + d(15 - 1)$

$$= a + 14d$$
- 3** **a** $17 - 6 = 11$
 $28 - 17 = 11$
 $39 - 28 = 11$
 $50 - 39 = 11$ Assuming that the pattern continues, consecutive terms differ by 11.
 $\therefore$ the sequence is arithmetic with $u_1 = 6$, $d = 11$.
- b** $u_n = u_1 + (n - 1)d$

$$= 6 + (n - 1)11$$

$$= 11n - 5$$
- c** $u_{50} = 11(50) - 5$

$$= 545$$
- d** Let $u_n = 325 = 11n - 5$

$$\therefore 330 = 11n$$

$$\therefore n = 30$$

 So, 325 is the 30th member.
- e** Let $u_n = 761 = 11n - 5$

$$\therefore 766 = 11n$$

$$\therefore n = 69\frac{7}{11}, \text{ but } n \text{ must be an integer, so } 761 \text{ is not a member of the sequence.}$$
- 4** **a** $83 - 87 = -4$ Assuming that the pattern continues, consecutive terms differ by -4 .
 $79 - 83 = -4$ $\therefore$ the sequence is arithmetic with $u_1 = 87$, $d = -4$.
 $75 - 79 = -4$
- b** $u_n = u_1 + (n - 1)d$

$$= 87 + (n - 1)(-4)$$

$$= 87 - 4n + 4$$

$$= 91 - 4n$$
- c** $u_{40} = 91 - 4(40)$

$$= 91 - 160$$

$$= -69$$
- d** Let $u_n = -297 = 91 - 4n$

$$\therefore 4n = 388$$

$$\therefore n = 97$$

 So, -297 is the 97th term of the sequence.
- 5** **a** $u_n = 3n - 2$, $u_{n+1} = 3(n + 1) - 2 = 3n + 1$
 $u_{n+1} - u_n = (3n + 1) - (3n - 2)$ Consecutive terms differ by 3.

$$= 3, \text{ a constant}$$
 $\therefore$ the sequence is arithmetic.
- b** $u_1 = 3(1) - 2 = 1$, $d = 3$
- c** $u_{57} = 3(57) - 2 = 169$
- d** Let $u_n = 450 = 3n - 2$, so $3n = 452$ and hence $n = 150\frac{2}{3}$.
 We try the two values on either side of $n = 150\frac{2}{3}$, which are $n = 150$ and $n = 151$:
 $u_{150} = 3(150) - 2 = 448$ and $u_{151} = 3(151) - 2 = 451$
 So, $u_{150} = 448$ is the largest term which is smaller than 450.
- 6** **a** $u_n = \frac{71 - 7n}{2} = 35\frac{1}{2} - \frac{7}{2}n$

$$u_{n+1} = \frac{71 - 7(n + 1)}{2} = \frac{71 - 7n - 7}{2} = \frac{64 - 7n}{2} = 32 - \frac{7}{2}n$$

$$u_{n+1} - u_n = (32 - \frac{7}{2}n) - (35\frac{1}{2} - \frac{7}{2}n) = -\frac{7}{2}, \text{ a constant}$$

 So, consecutive terms differ by $-\frac{7}{2}$. $\therefore$ the sequence is arithmetic.
- b** $u_1 = \frac{71 - 7(1)}{2} = 32$, $d = -\frac{7}{2}$
- c** $u_{75} = \frac{71 - 7(75)}{2} = -227$

$$\text{d Let } u_n = -200 = \frac{71 - 7n}{2} \quad \text{so } -400 = 71 - 7n \quad \therefore 7n = 471 \\ \therefore n = 67\frac{2}{7}$$

We try the two values on either side of $n = 67\frac{2}{7}$, which are $n = 67$ and $n = 68$:

$$u_{67} = \frac{71 - 7(67)}{2} = -199 \quad \text{and} \quad u_{68} = \frac{71 - 7(68)}{2} = -202\frac{1}{2}$$

So, the terms of the sequence are less than -200 for $n \geq 68$.

- 7 a** The terms are consecutive, so we equate common differences:

$$k - 32 = 3 - k \\ \therefore 2k = 35 \\ \therefore k = 17\frac{1}{2}$$

- c** The terms are consecutive, so we equate common differences:

$$(2k + 1) - (k + 1) = 13 - (2k + 1) \\ \therefore k = 12 - 2k \\ \therefore 3k = 12 \\ \therefore k = 4$$

- e** The terms are consecutive, so we equate common differences:

$$k^2 - k = (k^2 + 6) - k^2 \\ \therefore k^2 - k - 6 = 0 \\ \therefore (k + 2)(k - 3) = 0 \\ \therefore k = -2 \text{ or } 3$$

- 8 a** $u_7 = 41 \quad \therefore u_1 + 6d = 41 \quad \dots (1)$
 $u_{13} = 77 \quad \therefore u_1 + 12d = 77 \quad \dots (2)$

Solving simultaneously,

$$\begin{array}{r} -u_1 - 6d = -41 \\ u_1 + 12d = 77 \\ \hline \therefore 6d = 36 \quad \{\text{adding the equations}\} \\ \therefore d = 6 \end{array}$$

$$\text{So in (1), } u_1 + 6(6) = 41 \\ \therefore u_1 + 36 = 41 \quad \therefore u_1 = 5$$

$$\text{Now } u_n = u_1 + (n - 1)d \\ \therefore u_n = 5 + (n - 1)6 \\ \therefore u_n = 6n - 1$$

- c** $u_7 = 1 \quad \therefore u_1 + 6d = 1 \quad \dots (1)$
 $u_{15} = -39 \quad \therefore u_1 + 14d = -39 \quad \dots (2)$

Solving simultaneously,

$$\begin{array}{r} -u_1 - 6d = -1 \\ u_1 + 14d = -39 \\ \hline \therefore 8d = -40 \quad \{\text{adding the equations}\} \\ \therefore d = -5 \end{array}$$

$$\text{So in (1), } u_1 + 6(-5) = 1 \\ \therefore u_1 - 30 = 1 \quad \therefore u_1 = 31$$

$$\text{Now } u_n = u_1 + (n - 1)d \\ \therefore u_n = 31 + (n - 1)(-5) \\ \therefore u_n = 31 - 5n + 5 \\ \therefore u_n = -5n + 36$$

- b** The terms are consecutive, so we equate common differences:

$$7 - k = 10 - 7 \\ \therefore 7 - k = 3 \\ \therefore k = 4$$

- d** The terms are consecutive, so we equate common differences:

$$(2k + 3) - (k - 1) = (7 - k) - (2k + 3) \\ \therefore k + 4 = 4 - 3k \\ \therefore 4k = 0 \\ \therefore k = 0$$

- f** The terms are consecutive, so we equate common differences:

$$k - 5 = k^2 - 8 - k \\ \therefore k^2 - 2k - 3 = 0 \\ \therefore (k - 3)(k + 1) = 0 \\ \therefore k = -1 \text{ or } 3$$

- b** $u_5 = -2 \quad \therefore u_1 + 4d = -2 \quad \dots (1)$
 $u_{12} = -12\frac{1}{2} \quad \therefore u_1 + 11d = -12\frac{1}{2} \quad \dots (2)$

Solving simultaneously,

$$\begin{array}{r} -u_1 - 4d = 2 \\ u_1 + 11d = -12\frac{1}{2} \\ \hline \therefore 7d = -10\frac{1}{2} \quad \{\text{adding the equations}\} \\ \therefore d = -\frac{3}{2} \end{array}$$

$$\text{So in (1), } u_1 + 4(-\frac{3}{2}) = -2 \quad \therefore u_1 = 4$$

$$\text{Now } u_n = u_1 + (n - 1)d \\ \therefore u_n = 4 + (n - 1)(-\frac{3}{2}) \\ \therefore u_n = -\frac{3}{2}n + \frac{11}{2}$$

- d** $u_{11} = -16 \quad \therefore u_1 + 10d = -16 \quad \dots (1)$
 $u_8 = -11\frac{1}{2} \quad \therefore u_1 + 7d = -11\frac{1}{2} \quad \dots (2)$

Solving simultaneously,

$$\begin{array}{r} -u_1 - 10d = 16 \\ u_1 + 7d = -11\frac{1}{2} \\ \hline \therefore -3d = 4\frac{1}{2} \quad \{\text{adding the equations}\} \\ \therefore d = -\frac{3}{2} \end{array}$$

$$\text{So in (1), } u_1 + 10(-\frac{3}{2}) = -16$$

$$\therefore u_1 - 15 = -16 \quad \therefore u_1 = -1$$

$$\text{Now } u_n = u_1 + (n - 1)d \\ \therefore u_n = -1 + (n - 1)(-\frac{3}{2}) \\ \therefore u_n = -\frac{3}{2}n + \frac{1}{2}$$

- 9 a** Let the numbers be
 $5, 5 + d, 5 + 2d, 5 + 3d, 10$.
 Then $5 + 4d = 10$
 $\therefore 4d = 5$
 $\therefore d = \frac{5}{4} = 1\frac{1}{4}$
 So, the numbers are
 $5, 6\frac{1}{4}, 7\frac{1}{2}, 8\frac{3}{4}, 10$.
- b** Let the numbers be $-1, -1 + d, -1 + 2d, -1 + 3d, -1 + 4d, -1 + 5d, -1 + 6d, 32$.
 Then $-1 + 7d = 32$
 $\therefore 7d = 33$
 $\therefore d = \frac{33}{7} = 4\frac{5}{7}$
 So, the numbers are
 $-1, 3\frac{5}{7}, 8\frac{3}{7}, 13\frac{1}{7}, 17\frac{6}{7}, 22\frac{4}{7}, 27\frac{2}{7}, 32$.

- 10 a** $u_1 = 36, 35\frac{1}{3} - 36 = -\frac{2}{3},$
 $34\frac{2}{3} - 35\frac{1}{3} = -\frac{2}{3}$
 So, $d = -\frac{2}{3}$.
- b** $u_n = u_1 + (n - 1)d$
 $\therefore -30 = 36 + (n - 1)(-\frac{2}{3})$ {letting $u_n = -30$ }
 $\therefore -66 = -\frac{2}{3}n + \frac{2}{3}$
 $\therefore \frac{2}{3}n = 66\frac{2}{3}$
 $\therefore n = 100$ So, -30 is the 100th term of the sequence.

- 11** $u_1 = 23, 36 - 23 = 13$
 $49 - 36 = 13$
 $62 - 49 = 13$
 so $d = 13$
- $u_n = u_1 + (n - 1)d$
 $\therefore u_n = 23 + (n - 1)13$
 $= 23 + 13n - 13$
 $\therefore u_n = 13n + 10$
- Let $u_n = 100\,000$
 $= 13n + 10$
 $\therefore 99\,990 = 13n$
 $\therefore n = 7691\frac{7}{13}$

We try the two values on either side of $n = 7691\frac{7}{13}$, which are $n = 7691$ and $n = 7692$:

$$u_{7691} = 13(7691) + 10 = 99\,993 \quad \text{and} \quad u_{7692} = 13(7692) + 10 = 100\,006$$

So, the first term to exceed 100 000 is $u_{7692} = 100\,006$.

- 12 a** *Month 1:* 5 cars *Month 2:* $5 + 13 = 18$ cars *Month 3:* $18 + 13 = 31$ cars
Month 4: $31 + 13 = 44$ cars *Month 5:* $44 + 13 = 57$ cars *Month 6:* $57 + 13 = 70$ cars
- b** Every month after the first, the factory assembles 13 cars, so the difference between successive months is always 13. Thus we have an arithmetic sequence with $u_1 = 5$ and $d = 13$.
- c** $u_n = u_1 + (n - 1)d$
 $= 5 + (n - 1) \times 13$
 $= 13n - 8$
 $\therefore u_{12} = 13 \times 12 - 8$ {12 months = 1 year}
 $= 148$
 So, 148 cars are made in the first year.
- d** $u_n = 250 = 13n - 8$
 $\therefore 258 = 13n$
 $\therefore n = \frac{258}{13} \approx 19.85$
 So, the 250th car is made in the 20th month.

- 13 a** $41 - 34 = 48 - 41 = 55 - 48 = 7$
 Assuming the pattern continues, there is a common difference of 7, and so the number of Valéria's friends forms an arithmetic sequence with $u_1 = 34$ and $d = 7$.
- b** $u_n = u_1 + (n - 1)d$
 $= 34 + (n - 1) \times 7$
 $= 27 + 7n$
 $\therefore u_{12} = 27 + 7 \times 12 = 111$
 So, after 12 weeks Valéria will have 111 online friends.
- c** $u_n = 150 = 27 + 7n$
 $\therefore 123 = 7n$
 $\therefore n = \frac{123}{7} \approx 17.57$
 So, Valéria will have 150 online friends after the 18th week.

- 14 a** *July 1st:* $100 - 2.7 \times 1 = 97.3$ tonnes of hay
July 2nd: $100 - 2.7 \times 2 = 94.6$ tonnes of hay
July 3rd: $100 - 2.7 \times 3 = 91.9$ tonnes of hay
- b** $94.6 - 97.3 = 91.9 - 94.6 = -2.7$
 So $d = -2.7$, which means the cows eat 2.7 tonnes of hay per day.
- c** $u_{25} = 100 - 2.7 \times 25 = 32.5$ tonnes
 So, at the end of July 25th there are 32.5 tonnes of hay remaining in the barn.

d July has 31 days, so the end of day 31 is the start of August.

$$u_{31} = 100 - 2.7 \times 31 = 16.3 \text{ tonnes.}$$

Hence there are 16.3 tonnes of hay in the barn at the beginning of August.

So, it will take approximately 30.5 years.

- 1 a** The series is arithmetic with

$$S_n = \frac{n}{2} (2u_1 + (n-1)d)$$

$$\begin{aligned} \text{So, } S_{20} &= \frac{20}{2} (2 \times 3 + 19 \times 4) \\ &= 10(6 + 76) \\ &= 820 \end{aligned}$$

- c** The series is arithmetic with
 $u_1 = 100, \quad d = -7, \quad n = 40$

$$S_n = \frac{n}{2} (2u_1 + (n-1)d)$$

$$\begin{aligned} \text{So, } S_{40} &= \frac{40}{2} (2 \times 100 + 39 \times (-7)) \\ &= 20(200 - 273) \\ &= -1460 \end{aligned}$$

- 2 a** The series is arithmetic with
 $u_1 = 5, \quad d = 3, \quad u_n = 101$

Since $u_n = 101$,

then $u_1 + (n-1)d = 101$

$$\therefore 5 + 3(n-1) = 101$$

$$\therefore 5 + 3n - 3 = 101$$

$$\therefore 3n = 99$$

$$\therefore n = 33$$

$$\begin{aligned} \text{So, } S_n &= \frac{n}{2} (u_1 + u_n) \\ &= \frac{33}{2} (5 + 101) \\ &= 1749 \end{aligned}$$

- c** The series is arithmetic with
 $u_1 = 8, \quad d = \frac{5}{2}, \quad u_n = 83$

Since $u_n = 83$,

then $u_1 + (n-1)d = 83$

$$\therefore 8 + \frac{5}{2}(n-1) = 83$$

$$\therefore \frac{5}{2}n - \frac{5}{2} = 75$$

$$\therefore \frac{5}{2}n = \frac{155}{2}$$

$$\therefore n = 31$$

- b** The series is arithmetic with

$$u_1 = \frac{1}{2}, \quad d = \frac{5}{2}, \quad n = 50$$

$$S_n = \frac{n}{2} (2u_1 + (n-1)d)$$

$$\begin{aligned} \text{So, } S_{50} &= \frac{50}{2} \left(2 \times \frac{1}{2} + 49 \times \frac{5}{2} \right) \\ &= 25(1 + 122\frac{1}{2}) \\ &= 3087\frac{1}{2} \end{aligned}$$

- d** The series is arithmetic with

$$S_n = \frac{n}{2} (2u_1 + (n-1)d)$$

$$\begin{aligned} \text{So, } S_{80} &= \frac{80}{2} \left(2 \times 50 + 79 \times \left(-\frac{3}{2}\right) \right) \\ &= 40(100 - \frac{237}{2}) \\ &= -740 \end{aligned}$$

- b** The series is arithmetic with

$$u_1 = 50, \quad d = -\frac{1}{2}, \quad u_n = -20$$

Since $u_n = -20$,

then $u_1 + (n-1)d = -20$

$$\therefore 50 + \left(-\frac{1}{2}\right)(n-1) = -20$$

$$\therefore -\frac{1}{2}n + \frac{1}{2} = -70$$

$$\therefore -\frac{1}{2}n = -\frac{141}{2}$$

$$\therefore n = 141$$

$$\text{So, } S_n = \frac{n}{2} (u_1 + u_n)$$

$$\begin{aligned} &= \frac{141}{2} (50 + (-20)) \\ &= 2115 \end{aligned}$$

$$\begin{aligned} \text{So, } S_n &= \frac{n}{2} (u_1 + u_n) \\ &= \frac{31}{2} (8 + 83) \\ &= 1410\frac{1}{2} \end{aligned}$$

$$3 \quad \mathbf{a} \quad \sum_{k=1}^{10} (2k+5) = 7 + 9 + 11 + \dots + 25$$

This series is arithmetic with $u_1 = 7$, $d = 2$, and $n = 10$.

$$\therefore \text{sum} = \frac{n}{2} [2u_1 + (n-1)d] = \frac{10}{2} [14 + 9 \times 2] = 160$$

$$\mathbf{b} \quad \sum_{k=1}^{15} (k-50) = (-49) + (-48) + (-47) + \dots + (-35)$$

This series is arithmetic with $u_1 = -49$, $d = 1$, and $n = 15$.

$$\therefore \text{sum} = \frac{n}{2} [2u_1 + (n-1)d] = \frac{15}{2} [-98 + 14 \times 1] = -630$$

$$\mathbf{c} \quad \sum_{k=1}^{20} \left(\frac{k+3}{2} \right) = 2 + \frac{5}{2} + 3 + \dots + \frac{23}{2}$$

This series is arithmetic with $u_1 = 2$, $r = \frac{1}{2}$, and $n = 20$.

$$\therefore \text{sum} = \frac{n}{2} [2u_1 + (n-1)d] = \frac{20}{2} [4 + 19 \times \frac{1}{2}] = 135$$

$$4 \quad u_1 = 5, \quad n = 7, \quad u_n = 53$$

$$\begin{aligned} S_n &= \frac{n}{2} (u_1 + u_n) \\ &= \frac{7}{2} (5 + 53) \\ &= 203 \end{aligned}$$

$$5 \quad u_1 = 6, \quad n = 11, \quad u_n = -27$$

$$\begin{aligned} S_n &= \frac{n}{2} (u_1 + u_n) \\ &= \frac{11}{2} (6 + (-27)) \\ &= -115\frac{1}{2} \end{aligned}$$

$$6 \quad \text{The total number of bricks can be expressed as an arithmetic series: } 1 + 2 + 3 + 4 + \dots + n$$

We know that the total number of bricks is 171, so $S_n = 171$.

Also, $u_1 = 1$, $d = 1$ and we need to find n , the number of members (layers) of the series.

$$S_n = \frac{n}{2} (2u_1 + (n-1)d) = 171$$

$$\therefore \frac{n}{2} (2 \times 1 + (n-1) \times 1) = 171$$

$$\therefore n(2 + n - 1) = 342$$

$$\therefore n(n+1) = 342$$

$$\therefore n^2 + n - 342 = 0$$

$$\therefore (n-18)(n+19) = 0$$

$$\therefore n = -19 \text{ or } 18$$

But $n > 0$, so $n = 18$. So, there are 18 layers placed.

$$7 \quad \text{The total number of seats in } n \text{ rows can be expressed as an arithmetic series:}$$

$$22 + 23 + 24 + \dots + u_n$$

Row 1 has 22 seats, so $u_1 = 22$. Row 2 has 23 seats, so $d = 1$.

$$\begin{aligned} S_n &= \frac{n}{2} (2u_1 + (n-1)d) \\ &= \frac{n}{2} (2 \times 22 + 1(n-1)) \\ &= \frac{n}{2} (44 + n - 1) \end{aligned}$$

$$\therefore S_n = \frac{n}{2} (n + 43) \text{ which is the total number of seats in } n \text{ rows.}$$

$$\begin{aligned} \mathbf{a} \quad \text{Number of seats in row 44 of one section} &= \frac{\text{total no. of seats}}{\text{in every row}} - \frac{\text{no. of seats in the}}{\text{first 43 rows}} \\ &= S_{44} - S_{43} \\ &= \frac{44}{2} (44 + 43) - \frac{43}{2} (43 + 43) \\ &= 1914 - 1849 \\ &= 65 \end{aligned}$$

- b** Number of seats in a section = $S_{44} = 1914$ (from **a**)
c Number of seats in 25 sections = $S_{44} \times 25 = 1914 \times 25 = 47\,850$

- 8 a** The first 50 multiples of 11 can be expressed as an arithmetic series:
 $11 + 22 + 33 + \dots + u_{50}$ where $u_1 = 11$, $d = 11$, $n = 50$

$$S_n = \frac{n}{2}(2u_1 + (n-1)d) \quad \therefore S_{50} = \frac{50}{2}(2 \times 11 + 11(50-1))$$

$$= 25(22 + 539)$$

$$= 14\,025$$

- b** The multiples of 7 between 0 and 1000 can be expressed as an arithmetic series:
 $7 + 14 + 21 + 28 + \dots + u_n$ where $u_1 = 7$, $d = 7$
 To find u_n , we need to find the largest multiple of 7 less than 1000.

Now $\frac{1000}{7} \approx 142.9$, so $u_n = 142 \times 7 = 994$

But $u_n = u_1 + (n-1)d$

$\therefore 994 = 7 + 7(n-1)$

$\therefore 987 = 7n - 7$

$\therefore 7n = 994$

$\therefore n = 142$

So, $S_{142} = \frac{142}{2}(7 + 994) = 71\,071$

- c** The integers between 1 and 100 which are not divisible by 3 can be expressed as:
 $1, 2, 4, 5, 7, 8, \dots, 100$ where $u_1 = 1$, $u_n = 100$.

Alternatively, these integers can be expressed as two separate arithmetic series:

$S_A = 1 + 4 + 7 + \dots + 97 + 100$ where $u_1 = 1$, $d = 3$, $u_n = 100$
 and $S_B = 2 + 5 + 8 + \dots + 95 + 98$ where $u_1 = 2$, $d = 3$, $u_n = 98$

Now for S_A , $u_n = u_1 + (n-1)d$ and for S_B , $u_n = u_1 + (n-1)d$

$\therefore 100 = 1 + 3(n-1)$ $\therefore 98 = 2 + 3(n-1)$

$\therefore 99 = 3n - 3$ $\therefore 96 = 3n - 3$

$\therefore 3n = 102$ $\therefore 3n = 99$

$\therefore n = 34$ $\therefore n = 33$

So, $S_A = \frac{34}{2}(1 + 100) = 1717$ and $S_B = \frac{33}{2}(2 + 98) = 1650$

The total sum = $S_A + S_B = 1717 + 1650 = 3367$

- 9** The series of odd numbers can be expressed as an arithmetic series:

$1 + 3 + 5 + 7 + \dots$ where $u_1 = 1$, $d = 2$

a Now $u_n = u_1 + (n-1)d = 1 + 2(n-1)$

$\therefore u_n = 2n - 1$

- b** We need to show that S_n is n^2 .

The sum of the first n odd numbers can be expressed as an arithmetic series:

$1 + 3 + 5 + 7 + \dots + (2n-1)$ {using $u_n = 2n - 1$ from **a**}

So, $S_n = \frac{n}{2}(u_1 + u_n)$

$= \frac{n}{2}(1 + (2n-1))$

$= \frac{n}{2}(2n)$ Hence $S_n = n^2$ as required.

c $S_1 = 1 = 1 = 1^2 = n^2$ for $n = 1$ ✓

$S_2 = 1 + 3 = 4 = 2^2 = n^2$ for $n = 2$ ✓

$S_3 = 1 + 3 + 5 = 9 = 3^2 = n^2$ for $n = 3$ ✓

$S_4 = 1 + 3 + 5 + 7 = 16 = 4^2 = n^2$ for $n = 4$ ✓

- 10** $u_6 = 21$, $S_{17} = 0$. We need to find u_1 and u_2 .

$$S_n = \frac{n}{2}(2u_1 + (n-1)d)$$

$$\therefore S_{17} = \frac{17}{2}(2u_1 + 16d) = 0$$

$$\therefore u_1 + 8d = 0$$

$$\therefore u_1 = -8d \quad \dots (1)$$

$$\text{Also, } u_n = u_1 + (n-1)d$$

$$\therefore u_6 = u_1 + 5d$$

$$\therefore 21 = -8d + 5d \quad \{\text{using (1)}\}$$

$$\therefore 21 = -3d$$

$$\therefore d = -7$$

$$\text{So, } u_1 = -8(-7) = 56 \text{ and } u_2 = 56 - 7 = 49$$

The first two terms are 56 and 49.

- 11** Let the three consecutive terms be $x - d$, x , and $x + d$.

$$\text{Now, sum of terms} = 12$$

$$\therefore (x - d) + x + (x + d) = 12$$

$$\therefore 3x = 12$$

$$\therefore x = 4$$

$$\text{So, the terms are } 4 - d, 4, 4 + d$$

$$\text{So, the three terms could be } 4 - 6, 4, 4 + 6, \text{ which are } -2, 4, 10$$

$$\text{or } 4 - (-6), 4, 4 + (-6), \text{ which are } 10, 4, -2.$$

$$\text{Also, product of terms} = -80$$

$$\therefore (4 - d)4(4 + d) = -80$$

$$\therefore 4(4^2 - d^2) = -80$$

$$\therefore 16 - d^2 = -20$$

$$\therefore d^2 = 36 \quad \therefore d = \pm 6$$

- 12** Let the five consecutive terms be $n - 2d$, $n - d$, n , $n + d$, $n + 2d$.

$$\text{Now, sum of terms} = 40 \quad \therefore (n - 2d) + (n - d) + n + (n + d) + (n + 2d) = 40$$

$$\therefore 5n = 40$$

$$\therefore n = 8$$

$$\text{So the terms are } 8 - 2d, 8 - d, 8, 8 + d, 8 + 2d$$

$$\text{Also, the product of the first, middle and last terms} = (8 - 2d) \times 8 \times (8 + 2d) = 224$$

$$\therefore 8(8^2 - 4d^2) = 224$$

$$\therefore 64 - 4d^2 = 28$$

$$\therefore 4d^2 = 36$$

$$\therefore d^2 = 9$$

$$\therefore d = \pm 3$$

$$\text{So, the five terms could be } 8 - 2(3), 8 - 3, 8, 8 + 3, 8 + 2(3), \text{ which are } 2, 5, 8, 11, 14$$

$$\text{or } 8 - 2(-3), 8 - (-3), 8, 8 + (-3), 8 + 2(-3), \text{ which are } 14, 11, 8, 5, 2.$$

- 13** 11, 14, 17, 20, is arithmetic with $u_1 = 11$, $d = 3$

$$\therefore S_n = \frac{n}{2}(2u_1 + (n-1)d)$$

$$= \frac{n}{2}(22 + 3(n-1))$$

$$= \frac{n}{2}(3n + 19)$$

$$\text{Suppose } S_n = 2000$$

$$\therefore \frac{n}{2}(3n + 19) = 2000$$

$$\therefore 3n^2 + 19n = 4000$$

Using technology to list the terms of $3n^2 + 19n$:

$$n = 33 \text{ gives } 3n^2 + 19n = 3894 \quad \therefore S_{33} = 1947$$

$$n = 34 \text{ gives } 3n^2 + 19n = 4114 \quad \therefore S_{34} = 2057$$

$\therefore$ Henk would sell the 2000th TV set in week 34.

14 a $S_n = \frac{n(3n + 11)}{2}$

$$\therefore S_1 = u_1 = \frac{1(14)}{2} = 7$$

$$\text{and } S_2 = u_1 + u_2 = \frac{2(17)}{2} = 17$$

$$\therefore u_1 = 7 \text{ and } u_2 = 10$$

b $u_1 = 7$ and $d = 3$

$$\therefore u_{20} = u_1 + 19d = 7 + 19 \times 3 = 64$$

$\therefore$ the twentieth term is 64.

The difference between consecutive terms is constant for all n , so the sequence is arithmetic.

12 If a , b , and c are consecutive terms of a geometric sequence with constant ratio r , then $b = ar$ and $c = ar^2$ (1)

If a , b , and c are consecutive terms of an arithmetic sequence then

$$b - a = c - b$$

$$\therefore ar - a = ar^2 - ar \quad \{\text{using (1)}\}$$

$$\therefore ar^2 - 2ar + a = 0$$

$$\therefore a(r^2 - 2r + 1) = 0$$

$$\therefore a(r-1)^2 = 0$$

$$\therefore a = 0 \text{ or } r = 1$$

If $a = 0$ then $b = 0$ and $c = 0$ {using (1)}

In either case, $a = b = c$.

- 14** The first two terms of a geometric series are $2x$ and $x - 2$, so $u_1 = 2x$ and $r = \frac{x - 2}{2x}$

$$\text{Now } S = \frac{u_1}{1 - r} = \frac{2x}{1 - (\frac{x-2}{2x})}$$

$$= \frac{4x^2}{2x - (x - 2)}$$

$$\therefore 28x^2 = 18x + 36$$

$$\therefore 28x^2 - 18x - 36 = 0$$

$$= \frac{-\frac{1}{2}}{3}$$

$$= \frac{5}{3}$$

$$= -\frac{1}{6}$$

$$|r| < 1 \text{ only when } x = \frac{3}{2}, \text{ so } x = \frac{3}{2} \text{ is the only solution.}$$

- 15** a , b , and c are arithmetic, so $a - b = b - c = d$ where d is a constant.

$$\begin{aligned} \mathbf{a} \quad (c + a) - (b + c) &= c + a - b - c \\ &= a - b \\ &= d \end{aligned}$$

$$\begin{aligned} (a + b) - (c + a) &= a + b - c - a \\ &= b - c \\ &= d \end{aligned}$$

$\therefore$ the differences between the terms are equal.

$\therefore b + c$, $c + a$, and $a + b$ are also consecutive terms of an arithmetic sequence.

$$\mathbf{b} \quad \frac{1}{\sqrt{b} + \sqrt{c}} = \frac{1}{(\sqrt{b} + \sqrt{c})(\sqrt{b} - \sqrt{c})} = \frac{\sqrt{b} - \sqrt{c}}{b - c} = \frac{\sqrt{b} - \sqrt{c}}{d} \quad \dots (1)$$

Using (2) and (1):

$$\begin{aligned} \frac{1}{\sqrt{c} + \sqrt{a}} - \frac{1}{\sqrt{b} + \sqrt{c}} &= \frac{\sqrt{c} - \sqrt{a}}{-2d} - \frac{\sqrt{b} - \sqrt{c}}{d} = \frac{\sqrt{a} - \sqrt{c} - 2\sqrt{b} + 2\sqrt{c}}{2d} \\ &= \frac{\sqrt{a} - 2\sqrt{b} + \sqrt{c}}{2d} \end{aligned}$$

Using (3) and (2):

$$\begin{aligned} \frac{1}{\sqrt{a} + \sqrt{b}} - \frac{1}{\sqrt{c} + \sqrt{a}} &= \frac{\sqrt{a} - \sqrt{b}}{d} - \frac{\sqrt{c} - \sqrt{a}}{-2d} = \frac{2\sqrt{a} - 2\sqrt{b} + \sqrt{c} - \sqrt{a}}{2d} \\ &= \frac{\sqrt{a} - 2\sqrt{b} + \sqrt{c}}{2d} \end{aligned}$$

$\therefore$ the differences between the terms are equal.

$\therefore \frac{1}{\sqrt{b} + \sqrt{c}}, \frac{1}{\sqrt{c} + \sqrt{a}}$ and $\frac{1}{\sqrt{a} + \sqrt{b}}$ are also consecutive terms of an arithmetic sequence.

REVIEW SET 7C

1 $u_n = 68 - 5n$

a $u_{n+1} - u_n = [68 - 5(n + 1)] - [68 - 5n]$
 $= 68 - 5n - 5 - 68 + 5n$
 $= -5 \quad \text{for all } n$

b $u_1 = 68 - 5(1) = 63$, $d = -5$

c $u_{37} = 68 - 5(37) = -117$

$\therefore$ the sequence is arithmetic with common difference $d = -5$.

d Let $u_n = -200$, and we need to find n .

$$u_n = 68 - 5n = -200$$

$$\therefore 5n = 268$$

$$\therefore n = 53\frac{3}{5}$$

We try the two values on either side of $n = 53\frac{3}{5}$, which are $n = 53$ and $n = 54$:

$$\begin{aligned} u_{53} &= 68 - 5(53) & \text{and} & & u_{54} &= 68 - 5(54) \\ &= -197 & & & &= -202 \end{aligned}$$

So, the first term of the sequence less than -200 is $u_{54} = -202$.

2 a 3, 12, 48, 192,

$$\frac{12}{3} = 4 \quad \frac{48}{12} = 4 \quad \frac{192}{48} = 4$$

Assuming the pattern continues, consecutive terms have a common ratio of 4.

$\therefore$ the sequence is geometric with $u_1 = 3$ and $r = 4$.

$$\begin{aligned} \mathbf{b} \quad u_n &= u_1 r^{n-1} \\ \therefore u_n &= 3 \times 4^{n-1} \\ \therefore u_9 &= 3 \times 4^8 = 196\,608 \end{aligned}$$

$$\begin{aligned} \mathbf{3} \quad u_7 &= 31 \quad \therefore u_1 + 6d = 31 \quad \dots (1) \\ u_{15} &= -17 \quad \therefore u_1 + 14d = -17 \quad \dots (2) \\ \text{So, } (u_1 + 14d) - (u_1 + 6d) &= -17 - 31 \quad \{(2) - (1)\} \\ \therefore 8d &= -48 \\ \therefore d &= -6 \\ \text{So in (1), } u_1 + 6(-6) &= 31 \quad \text{Now } u_n = u_1 + (n-1)d \\ \therefore u_1 - 36 &= 31 \quad \therefore u_n = 67 + (n-1)(-6) \\ \therefore u_1 &= 67 \quad \therefore u_n = 67 - 6n + 6 \\ &\quad \therefore u_n = 73 - 6n \\ \text{So, } u_{34} &= 73 - 6(34) = -131 \end{aligned}$$

$$\begin{aligned} \mathbf{4} \quad \mathbf{a} \quad &4 + 11 + 18 + 25 + \dots \\ \text{The series is arithmetic with } u_1 &= 4, \quad d = 7, \quad u_k = u_1 + (k-1)d \\ &= 4 + 7(k-1) \\ &= 7k - 3 \end{aligned}$$

$$\text{So, the series is } \sum_{k=1}^n (7k - 3).$$

$$\begin{aligned} \mathbf{b} \quad &\frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \dots \\ \text{The series is geometric with } u_1 &= \frac{1}{4}, \quad r = \frac{1}{2}, \\ u_k &= u_1 r^{k-1} = \frac{1}{4} \times \left(\frac{1}{2}\right)^{k-1} = \left(\frac{1}{2}\right)^2 \left(\frac{1}{2}\right)^{k-1} = \left(\frac{1}{2}\right)^{k+1} \\ \text{So, the series is } &\sum_{k=1}^n \left(\frac{1}{2}\right)^{k+1}. \end{aligned}$$

$$\begin{aligned} \mathbf{5} \quad \mathbf{a} \quad &\sum_{k=1}^8 \left(\frac{31-3k}{2}\right) = 14 + 12\frac{1}{2} + 11 + 9\frac{1}{2} + 8 + 6\frac{1}{2} + 5 + 3\frac{1}{2} \\ \text{This series is arithmetic with } u_1 &= 14, \quad n = 8, \quad \text{and } u_n = 3\frac{1}{2}. \\ \therefore \text{ the sum is } &\frac{8}{2}(14 + 3\frac{1}{2}) = 70 \end{aligned}$$

$$\begin{aligned} \mathbf{b} \quad &\sum_{k=1}^{15} 50(0.8)^{k-1} \approx 50 + 40 + 32 + \dots + 3.436 + 2.749 + 2.199 \\ \text{This series is geometric with } u_1 &= 50, \quad r = 0.8, \quad \text{and } n = 15. \\ \therefore \text{ the sum is } &\frac{50 [1 - (0.8)^{15}]}{1 - 0.8} \approx 241 \end{aligned}$$

$$\mathbf{c} \quad \sum_{k=7}^{\infty} 5\left(\frac{2}{5}\right)^{k-1} = 5\left(\frac{2}{5}\right)^6 + 5\left(\frac{2}{5}\right)^7 + 5\left(\frac{2}{5}\right)^8 + \dots$$

$$\text{The series is an infinite geometric series with } u_1 = 5\left(\frac{2}{5}\right)^6, \quad r = \frac{2}{5}$$

$$\begin{aligned} \therefore S &= \frac{u_1}{1-r} = \frac{5\left(\frac{2}{5}\right)^6}{\frac{3}{5}} \\ &= \frac{2^6}{3 \times 5^4} \\ &= \frac{64}{1875} \end{aligned}$$

- 6** $11 + 16 + 21 + 26 + \dots$ is arithmetic with $u_1 = 11$, $d = 5$

$$\begin{aligned} \therefore S_n &= \frac{n}{2} (2u_1 + (n-1)d) && \text{Given } S_n = 450, \text{ we need to find } n, \\ &= \frac{n}{2} (2 \times 11 + 5(n-1)) && \text{so } S_n = \frac{n}{2} (5n + 17) = 450 \\ &= \frac{n}{2} (22 + 5n - 5) && \therefore \frac{5}{2}n^2 + \frac{17}{2}n - 450 = 0 \\ &= \frac{n}{2} (5n + 17) && \therefore 5n^2 + 17n - 900 = 0 \\ & && \therefore n \approx -15.2, 11.8 \quad \{\text{using technology}\} \\ & && \text{But } n > 0, \text{ so } n \approx 11.8 \end{aligned}$$

We try the two values on either side of $n \approx 11.8$, which are $n = 11$ and $n = 12$:

$$S_{11} = \frac{11}{2} (5(11) + 17) = 396 \quad \text{and} \quad S_{12} = \frac{12}{2} (5(12) + 17) = 462$$

$\therefore$ 12 terms of the series are required to exceed a sum of 450.

- 7 a** $u_{n+1} = u_1 \times r^n$ where $u_1 = 12\,500$, $r = 1 + \frac{0.0825}{2} = 1.041\,25$, $n = 5 \times 2 = 10$

$$\begin{aligned} \text{So, } u_{n+1} &= 12\,500 \times (1.041\,25)^{10} \\ &\approx 18\,726.65 \end{aligned} \quad \text{The value of the investment is } \pounds 18\,726.65.$$

- b** $u_{n+1} = u_1 \times r^n$ where $u_1 = 12\,500$, $r = 1 + \frac{0.0825}{12} = 1.006\,875$, $n = 5 \times 12 = 60$

$$\begin{aligned} \text{So, } u_{n+1} &= 12\,500 \times (1.006\,875)^{60} \\ &\approx 18\,855.74 \end{aligned} \quad \text{The value of the investment is } \pounds 18\,855.74.$$

- 8 a** Let the terms of the geometric series be $u_1, u_1r, u_1r^2, \dots$

$$\begin{aligned} \text{Then } u_1 + u_1r &= 90 && \text{and } u_1r^2 = 24 \\ \therefore u_1(1+r) &= 90 && \therefore u_1 = \frac{24}{r^2} \quad \dots (2) \\ \therefore u_1 &= \frac{90}{1+r} \quad \dots (1) \end{aligned}$$

$$\begin{aligned} \text{Equating (1) and (2) gives } \frac{90}{1+r} &= \frac{24}{r^2} \\ \therefore 90r^2 &= 24r + 24 \\ \therefore 90r^2 - 24r - 24 &= 0 \\ \therefore 6(15r^2 - 4r - 4) &= 0 \\ \therefore 6(5r + 2)(3r - 2) &= 0 \\ \therefore r &= -\frac{2}{5} \text{ or } \frac{2}{3} \end{aligned}$$

$$\text{Using (2), if } r = -\frac{2}{5} \text{ then } u_1 = \frac{24}{(-\frac{2}{5})^2} = \frac{24}{\frac{4}{25}} = 150$$

$$\text{if } r = \frac{2}{3} \text{ then } u_1 = \frac{24}{(\frac{2}{3})^2} = \frac{24}{\frac{4}{9}} = 54$$

$$\therefore \text{ either } u_1 = 150, r = -\frac{2}{5} \text{ or } u_1 = 54, r = \frac{2}{3}$$

- b** Since $|r| < 1$ in each case, both series converge.

$$\text{When } u_1 = 150, r = -\frac{2}{5} \quad \text{When } u_1 = 54, r = \frac{2}{3}$$

$$\begin{aligned} \therefore S &= \frac{u_1}{1-r} && \therefore S = \frac{u_1}{1-r} \\ &= \frac{150}{\frac{7}{5}} && = \frac{54}{\frac{1}{3}} \\ &= \frac{750}{7} = 107\frac{1}{7} && = 162 \end{aligned}$$

- 9** Since Seve walks an additional 500 m = 0.5 km each week, we have an arithmetic sequence with $u_1 = 10$ and constant difference $d = 0.5$.

$$u_n = u_1 + (n - 1)d$$

$$\therefore u_n = 10 + (n - 1)0.5$$

a $u_{52} = 10 + (52 - 1)0.5 \quad \{52 \text{ weeks in a year}\}$
 $= 35.5$

$\therefore$ Seve walks 35.5 km in the last week.

- b** In total, Seve walks $10 + 10.5 + 11 + \dots + 35.5$, which is an arithmetic series.

$$S_n = \frac{n}{2}(u_1 + u_n)$$

$$\therefore S_{52} = \frac{52}{2}(10 + 35.5)$$

$$= 1183$$

$\therefore$ Seve walks 1183 km in total.

- 10 a** $\sum_{k=1}^{\infty} 50(2x - 1)^{k-1}$ is a geometric series with $r = 2x - 1$ and converges if $-1 < r < 1$

$$\therefore -1 < 2x - 1 < 1$$

$$\therefore 0 < 2x < 2$$

$$\therefore 0 < x < 1$$

- b** When $x = 0.3$, $2x - 1 = 0.6 - 1 = -0.4$

and $\sum_{k=1}^{\infty} 50(2x - 1)^{k-1} = 50(-0.4)^0 + 50(-0.4)^1 + 50(-0.4)^2 + \dots$

which is geometric with $u_1 = 50$, $r = -0.4$

Now as $0 < 0.3 < 1$, the series converges and $S = \frac{u_1}{1 - r} = \frac{50}{1 + 0.4} = \frac{50}{\frac{7}{5}} = 35\frac{5}{7}$

- 11** Since a, b, c, d , and e are consecutive terms of an arithmetic sequence,

$$b - a = c - b = d - c = e - d$$

Taking the first and last equalities, $b - a = e - d$

$$\therefore b + d = a + e$$

Taking the middle equalities, $c - b = d - c$

$$\therefore 2c = b + d$$

$$\therefore a + e = b + d = 2c$$

- 12** Let the geometric sequence be $1, \underbrace{r, r^2, r^3, \dots, r^{n-1}, r^n}_{n \text{ terms}}, 2$

$$\therefore r^{n+1} = 2 \text{ and so } r = 2^{\frac{1}{n+1}}$$

The required sum is $r + r^2 + r^3 + \dots + r^{n-1} + r^n$,

which is geometric with $u_1 = r$, ' r ' = r , and ' n ' = n .

$$\therefore S_n = \frac{u_1(r^n - 1)}{r - 1}$$

$$= \frac{r(r^n - 1)}{r - 1}$$

$$= \frac{r^{n+1} - r}{r - 1}$$

$$= \frac{2 - 2^{\frac{1}{n+1}}}{2^{\frac{1}{n+1}} - 1}$$

- 13** Let the first three terms of the arithmetic sequence be $u_1, u_1 + d, u_1 + 2d$, and the first three terms of the geometric sequence be $u_1, u_1 r, u_1 r^2$.

The second terms are equal

$$\therefore u_1 + d = u_1 r$$

$$\therefore d = u_1(r - 1)$$

$$\therefore u_1 = \frac{d}{r - 1} \quad \dots (1)$$

$$\begin{aligned} \text{Now } \frac{u_1 r^2}{u_1 + 2d} &= \frac{\left(\frac{d}{r-1}\right)r^2}{\left(\frac{d}{r-1}\right) + 2d} \quad \{\text{using (1)}\} \\ &= \frac{dr^2}{d + 2d(r - 1)} \\ &= \frac{dr^2}{d(2r - 1)} \\ &= \frac{r^2}{2r - 1} \end{aligned}$$

$\therefore$ the third term of the geometric sequence is $\frac{r^2}{2r - 1}$ times the third term of the arithmetic sequence.

- 14** The value of $\underbrace{111\dots11}_{2n \text{ lots of } 1}$ is $1 + 10 + 10^2 + \dots + 10^{2n-1}$, which is a geometric series with $u_1 = 1, r = 10, 'n' = 2n$.

$$\begin{aligned} \therefore \text{the value of this sum is } S_1 &= \frac{u_1(r^n - 1)}{r - 1} = \frac{1(10^{2n} - 1)}{10 - 1} \\ &= \frac{10^{2n} - 1}{9} \end{aligned}$$

The value of $\underbrace{222\dots22}_{n \text{ lots of } 2}$ is $2 + 2 \times 10 + 2 \times 10^2 + \dots + 2 \times 10^{n-1}$,

which is a geometric series with $u_1 = 2, r = 10, 'n' = n$.

$$\begin{aligned} \therefore \text{the value of this sum is } S_2 &= \frac{u_1(r^n - 1)}{r - 1} = \frac{2(10^n - 1)}{10 - 1} \\ &= \frac{2 \times 10^n - 2}{9} \end{aligned}$$

$$\begin{aligned} \therefore \text{the value of } \underbrace{111\dots11}_{2n \text{ lots of } 1} - \underbrace{222\dots22}_{n \text{ lots of } 2} &= S_1 - S_2 = \frac{10^{2n} - 1}{9} - \frac{2 \times 10^n - 2}{9} \\ &= \frac{10^{2n} - 1 - 2 \times 10^n + 2}{9} \\ &= \frac{10^{2n} - 2 \times 10^n + 1}{9} \\ &= \frac{(10^n - 1)^2}{3^2} \\ &= \left(\frac{10^n - 1}{3}\right)^2 \end{aligned}$$

$10^n - 1 = \underbrace{99\dots9}_{n \text{ lots of } 9}$ is divisible by 3, so $\frac{10^n - 1}{3}$ is an integer

$\therefore \underbrace{111\dots11}_{2n \text{ lots of } 1} - \underbrace{222\dots22}_{n \text{ lots of } 2}$ is a perfect square.

COUNTING AND THE BINOMIAL EXPANSION

EXERCISE 8A

- 1 There are 3 paths from P to Q
 3 paths from Q to R
 2 paths from R to S
 $\therefore$ number of routes possible
 $= 3 \times 3 \times 2$ {product principle}
 $= 18$

From A there are 3 possible first leg paths, to W, X, or Y. Then there are 2 second leg paths to B.
 $\therefore$ total number $= 3 \times 2 = 6$ paths.

- 5 Any of the 8 teams could be ‘top’.
 Any of the remaining 7 could be second.
 Any of the remaining 6 could be third.
 Any of the remaining 5 could be fourth.
 $\therefore$ there are $8 \times 7 \times 6 \times 5$
 $= 1680$ ways.

Repetitions are allowed.
 $\therefore$ total number of ways
 $= 26 \times 26 \times 26 \times 10 \times 10 \times 10$
 $= 17\,576\,000$

- 2 a There are 4 choices for A. But once A is located, there is 1 choice for B, 1 for C, and 1 for D.
 $\therefore$ there are $4 \times 1 \times 1 \times 1 = 4$ ways.
- b There are 4 choices for A. But once A is located there are 2 choices for B. Once B is located there is 1 choice for C and 1 for D.
 $\therefore$ there are $4 \times 2 \times 1 \times 1 = 8$ ways.
- c There are 4 choices for A. Once A is located there are 3 choices for B. Once B is located there are 2 choices for C and then 1 for D.
 $\therefore$ there are $4 \times 3 \times 2 \times 1 = 24$ ways.

- 4 Any of the 7 teams could be in ‘top’ position. Then there are 6 left which could be in the ‘second’ position.
 So, there are $7 \times 6 = 42$ possible ways.

- 6 There are 5 digits to choose from.
- a Number of ways $= 5 \times 5 \times 5 = 125$
- b Number of ways $= 5 \times 4 \times 3 = 60$

- 8 a The 1st letter could go into either of the 2 boxes, and the second could go into either of the 2 boxes,
 $\therefore$ there are $2 \times 2 = 4$ ways.

These are:

Box X	Box Y
A, B	-
A	B
B	A
-	A, B

- b There are $3 \times 3 = 9$ ways.
- c There are $3 \times 3 \times 3 \times 3 = 81$ ways.

EXERCISE 8B

- 1 a There are $2 \times 2 + 3 \times 3$
 $= 13$ different paths
- c There are $2 + 4 \times 2 + 3 \times 3$
 $= 19$ different paths
- 2 There are $3 \times 2 + 3 \times 1 + 2 \times 2$
 $= 13$ different train journeys
- b There are $4 \times 2 + 3 \times 2 \times 2$
 $= 20$ different paths
- d There are $2 \times 2 + 2 \times 2 + 2 \times 3 \times 4$
 $= 32$ different paths

b If no vowels are used, there are 4 letters to choose from.

$\therefore$

4	3	2	1
---	---	---	---

 So, there are $4! = 24$ different arrangements.

$\therefore$ if at least one vowel must be used, there are $360 - 24$ {from **a**}
 $= 336$ different arrangements

c We first count the number of ways two vowels are adjacent.

A and O can be put together in $2!$ ways {AO or OA}

These vowels can be placed in any one of 3 positions {1st and 2nd, 2nd and 3rd, or 3rd and 4th}

The remaining 2 places can be filled from the other 4 letters in 4×3 different ways.

$\therefore$ two vowels are adjacent in $2! \times 3 \times 4 \times 3 = 72$ ways

$\therefore$ no two vowels are adjacent in $360 - 72 = 288$ ways

- 8** **a** If there are no restrictions the number of ways = $\binom{16}{5} = 4368$
- b** The three men can be chosen in $\binom{10}{3}$ ways and the 2 women in $\binom{6}{2}$ ways.
 $\therefore$ total number of ways = $\binom{10}{3} \times \binom{6}{2} = 120 \times 15 = 1800$ ways.
- c** If it contains all men, the number of ways = $\binom{10}{5} \times \binom{6}{0} = 252$
- d** If it contains at least 3 men it would contain 3 men and 2 women or 4 men and 1 woman or 5 men and 0 women and this can be done in $\binom{10}{3} \binom{6}{2} + \binom{10}{4} \binom{6}{1} + \binom{10}{5} \binom{6}{0}$ ways = 3312 ways.

 The 1 dentist can be chosen in $\binom{3}{1}$ ways
 The 2 others can be chosen in $\binom{7}{2}$ ways
 $\therefore$ the total number of ways = $\binom{6}{2} \times \binom{3}{1} \times \binom{7}{2} = 945$
- b** If it contains 2 doctors, 3 must be chosen from the other 10,
 $\therefore$ there are $\binom{6}{2} \binom{10}{3} = 1800$ ways.
- c** If it contains at least one person from each of the two professions this can be done in $\binom{9}{1} \binom{7}{4} + \binom{9}{2} \binom{7}{3} + \binom{9}{3} \binom{7}{2} + \binom{9}{4} \binom{7}{1} = 4347$ or $\binom{16}{5} - \binom{9}{0} \binom{7}{5} = 4347$
- 10** There are 20 points (for vertices) to choose from and any 2 form a line.
 This can be done in $\binom{20}{2}$ ways. But this count includes the 20 lines joining the vertices.
 $\therefore$ the number of diagonals = $\binom{20}{2} - 20 = 190 - 20 = 170$
- 11** **a** **i** $\binom{12}{2} = 66$ lines can be determined.
- ii** Of the lines in **a i** $\binom{1}{1} \binom{11}{1} = 11$ pass through B.
- b** **i** $\binom{12}{3} = 220$ triangles can be determined.
- ii** Of the triangles in **b i** $\binom{1}{1} \binom{11}{2} = 55$ have one vertex B.

- 12** The digits must be from 1 to 9. So, there are 9 of them, and we want any 4.
This can be done in $\binom{9}{4} = 126$ ways.
Once they have been selected they can be put in one ascending order
 $\therefore$ total number $= 126 \times 1 = 126$.
- 13** **a** The different committees of 4, consisting of selections from 5 men and 6 women *in all possible ways* are
(4 men, 0 women) or (3 men, 1 woman) or (2 men, 2 women) or (1 man, 3 women)
or (0 men, 4 women)
 $\therefore \binom{5}{4} \binom{6}{0} + \binom{5}{3} \binom{6}{1} + \binom{5}{2} \binom{6}{2} + \binom{5}{1} \binom{6}{3} + \binom{5}{0} \binom{6}{4} = \binom{11}{4}$ ← total number unrestricted
- b** The generalisation is:
 $\binom{m}{0} \binom{n}{r} + \binom{m}{1} \binom{n}{r-1} + \binom{m}{2} \binom{n}{r-2} + \dots + \binom{m}{r-2} \binom{n}{2} + \binom{m}{r-1} \binom{n}{1} + \binom{m}{r} \binom{n}{0} = \binom{m+n}{r}$
- 14** **a** Consider a simpler case of 4 people (A, B, C, and D) going into two equal groups.
AB CD (1) (1) and (6) are the same division.
AC BD (2) (2) and (5) are the same division.
AD BC (3) (3) and (4) are the same division.
BC AD (4)
BD AC (5) So, the number of ways is $\frac{1}{2}$ of $\binom{4}{2}$.
CD AB (6)
So, for 2 equal groups of 6, the number of ways $= \frac{1}{2}$ of $\binom{12}{6} \binom{6}{6}$
 $= \frac{1}{2} \times 924$
 $= 462$
- b** For 3 equal groups of 4, the number of ways $= \frac{1}{3!} \times \binom{12}{4} \times \binom{8}{4} \times \binom{4}{4}$
 $= 5775$
- 15** There is one point of intersection for every combination of 4 points (2 from A, 2 from B) as shown.
There are $\binom{10}{2} \times \binom{7}{2}$ ways to choose these points.
 $\therefore$ the maximum number of points of intersection (when none of the intersection points coincide) is $\binom{10}{2} \times \binom{7}{2} = 945$

- 16** There is one point of intersection for every combination of 4 points (no more than 2 from any one line) as shown.
 $\therefore$ the maximum number of points of intersection (when none of the intersection points coincide) is
 $\binom{10}{2} \binom{9}{2} \binom{8}{0} + \binom{10}{2} \binom{9}{0} \binom{8}{2} + \binom{10}{0} \binom{9}{2} \binom{8}{2}$
 $+ \binom{10}{2} \binom{9}{1} \binom{8}{1} + \binom{10}{1} \binom{9}{2} \binom{8}{1} + \binom{10}{1} \binom{9}{1} \binom{8}{2}$
 $= 12\,528$

- 17** **a** Each handshake occurs between 2 people. So we need the number of ways 2 people can be selected from 10.
 $\therefore$ the number of handshakes between committee members is $\binom{10}{2} = 45$.
A 10-sided polygon can be used to solve this problem by counting the total number of lines (including edges) between each pair of vertices. Each line represents a handshake between 2 of the 10 committee members.
- b** The number of handshakes between 273 delegates is $\binom{273}{2} = 37\,128$.
- c** The number of different orders in which the committee members can line up on stage is $10! = 3\,628\,800$.

 &= \binom{4}{r} x^{12-3r} q^r x^{-3r} \\
 &= \binom{4}{r} x^{12-6r} q^r

which has constant term $\binom{4}{2} q^2$ $\{12 - 6r = 0 \text{ when } r = 2\}$

$$\begin{aligned}
 \therefore \binom{8}{4} q^4 &= \binom{4}{2} q^2 \\
 \therefore 70q^4 - 6q^2 &= 0 \\
 \therefore q^2(70q^2 - 6) &= 0 \\
 \therefore 70q^2 - 6 &= 0 \quad \{q = 0 \text{ gives a trivial solution}\} \\
 \therefore q^2 &= \frac{6}{70} = \frac{3}{35} \\
 \therefore q &= \pm \sqrt{\frac{3}{35}}

MATHEMATICAL INDUCTION

EXERCISE 9A

1 The n th term of the sequence 3, 7, 11, 15, 19, ... is $4n - 1$ for $n \in \mathbb{Z}^+$.

2 a $3^1 = 3$ $1 + 2(1) = 3$ Our proposition is:
 $3^2 = 9$ $1 + 2(2) = 5$ $3^n > 1 + 2n$ for $n = 2, 3, 4, 5, \dots$
 $3^3 = 27$ $1 + 2(3) = 7$ or for all $n \in \mathbb{Z}^+$, $n \geq 2$
 $3^4 = 81$ $1 + 2(4) = 9$

b $11^1 - 1 = 10$ Our proposition is:
 $11^2 - 1 = 121 - 1 = 120$ $11^n - 1$ is divisible by 10 for all $n \in \mathbb{Z}^+$
 $11^3 - 1 = 1331 - 1 = 1330$
 $11^4 - 1 = 14641 - 1 = 14640$

c $7^1 + 2 = 7 + 2 = 9 = 3 \times 3$ Our proposition is:
 $7^2 + 2 = 49 + 2 = 51 = 3 \times 17$ $7^n + 2$ is divisible by 3 for all $n \in \mathbb{Z}^+$
 $7^3 + 2 = 343 + 2 = 345 = 3 \times 115$
 $7^4 + 2 = 2401 + 2 = 2403 = 3 \times 801$

d $(1 - \frac{1}{2}) = \frac{1}{2}$
 $(1 - \frac{1}{2})(1 - \frac{1}{3}) = \frac{1}{2} \times \frac{2}{3} = \frac{1}{3}$
 $(1 - \frac{1}{2})(1 - \frac{1}{3})(1 - \frac{1}{4}) = \frac{1}{2} \times \frac{2}{3} \times \frac{3}{4} = \frac{1}{4}$
 $(1 - \frac{1}{2})(1 - \frac{1}{3})(1 - \frac{1}{4})(1 - \frac{1}{5}) = \frac{1}{2} \times \frac{2}{3} \times \frac{3}{4} \times \frac{4}{5} = \frac{1}{5}$
 Our proposition is: $(1 - \frac{1}{2})(1 - \frac{1}{3})(1 - \frac{1}{4}) \dots \left(1 - \frac{1}{n+1}\right) = \frac{1}{n+1}$ for all $n \in \mathbb{Z}^+$

3 a $2 = 2 = 1 \times 2$ Our proposition is:
 $2 + 4 = 6 = 2 \times 3$ $2 + 4 + 6 + 8 + 10 + \dots + 2n = n(n+1)$ for all $n \in \mathbb{Z}^+$
 $2 + 4 + 6 = 12 = 3 \times 4$ $\uparrow$
 $2 + 4 + 6 + 8 = 20 = 4 \times 5$ nth term
 $2 + 4 + 6 + 8 + 10 = 30 = 5 \times 6$ $\therefore \sum_{i=1}^n 2i = n(n+1)$ for all $n \in \mathbb{Z}^+$

b $1! = 1$
 $1! + 2 \times 2! = 1 + 2(2) = 5$
 $1! + 2 \times 2! + 3 \times 3! = 1 + 4 + 18 = 23$
 $1! + 2 \times 2! + 3 \times 3! + 4 \times 4! = 1 + 4 + 18 + 96 = 119$
 where each number result is 1 less than a factorial number

$1 = 2! - 1$ Our proposition is:
 $5 = 3! - 1$ $1! + 2 \times 2! + 3 \times 3! + 4 \times 4! + \dots + n \times n! = (n+1)! - 1$
 $23 = 4! - 1$ for all $n \in \mathbb{Z}^+$
 $119 = 5! - 1$ $\therefore \sum_{i=1}^n i \times i! = (n+1)! - 1$ for all $n \in \mathbb{Z}^+$

c $\frac{1}{2!} = \frac{1}{2} = \frac{2! - 1}{2!}$
 $\frac{1}{2!} + \frac{2}{3!} = \frac{1}{2} + \frac{2}{6} = \frac{5}{6} = \frac{3! - 1}{3!}$
 $\frac{1}{2!} + \frac{2}{3!} + \frac{3}{4!} = \frac{1}{2} + \frac{2}{6} + \frac{3}{24} = \frac{23}{24} = \frac{4! - 1}{4!}$
 $\frac{1}{2!} + \frac{2}{3!} + \frac{3}{4!} + \frac{4}{5!} = \frac{1}{2} + \frac{2}{6} + \frac{3}{24} + \frac{4}{120} = \frac{119}{120} = \frac{5! - 1}{5!}$

Our proposition is: $\frac{1}{2!} + \frac{2}{3!} + \frac{3}{4!} + \frac{4}{5!} + \dots + \frac{n}{(n+1)!} = \frac{(n+1)! - 1}{(n+1)!}$ for all $n \in \mathbb{Z}^+$

$$\therefore \sum_{i=1}^n \frac{i}{(i+1)!} = \frac{(n+1)! - 1}{(n+1)!} \text{ for all } n \in \mathbb{Z}^+$$

d $\frac{1}{2 \times 5} = \frac{1}{10}$

$$\frac{1}{2 \times 5} + \frac{1}{5 \times 8} = \frac{1}{10} + \frac{1}{40} = \frac{5}{40} = \frac{1}{8} = \frac{2}{16}$$

$$\frac{1}{2 \times 5} + \frac{1}{5 \times 8} + \frac{1}{8 \times 11} = \frac{1}{10} + \frac{1}{40} + \frac{1}{88} = \frac{3}{22}$$

$$\frac{1}{2 \times 5} + \frac{1}{5 \times 8} + \frac{1}{8 \times 11} + \frac{1}{11 \times 14} = \frac{1}{7} = \frac{4}{28}$$

Our proposition is:

$$\frac{1}{2 \times 5} + \frac{1}{5 \times 8} + \frac{1}{8 \times 11} + \frac{1}{11 \times 14} + \dots + \frac{1}{(3n-1)(3n+2)} = \frac{n}{6n+4} \text{ for all } n \in \mathbb{Z}^+$$

$\{2, 5, 8, 11\}$ are arithmetic with $u_1 = 2, d = 3 \therefore u_n = 2 + (n-1)3 = 3n-1$

$$\therefore \sum_{i=1}^n \frac{1}{(3i-1)(3i+2)} = \frac{n}{6n+4} \text{ for all } n \in \mathbb{Z}^+$$

10, 16, 22, 28 is arithmetic
with $u_1 = 10, d = 6$

$$\begin{aligned} u_n &= u_1 + (n-1)d \\ &= 10 + 6(n-1) \\ &= 6n + 4 \end{aligned}$$

4 For $n = 1$

$$T_1 = 3 = 2 \times 1 + 1$$

For $n = 2$

$$T_2 = 5 = 2 \times 2 + 1$$

For $n = 3$

$$T_3 = 7 = 2 \times 3 + 1$$

Our proposition is: The maximum number of triangles for n points within the original triangle is given by $T_n = 2n + 1$ for all $n \in \mathbb{Z}^+$.

5 a

$n = 4$

$$C_4 = 8$$

$n = 5$

$$C_5 = 16$$

b When $n = 1, C_1 = 1 = 2^0 = 2^{1-1}$
 $n = 2, C_2 = 2 = 2^1 = 2^{2-1}$
 $n = 3, C_3 = 4 = 2^2 = 2^{3-1}$
 $n = 4, C_4 = 8 = 2^3 = 2^{4-1}$
 $n = 5, C_5 = 16 = 2^4 = 2^{5-1}$

So, from the cases $n = 1, 2, 3, 4, 5$,
our conjecture is:

The number of regions for n points
placed around a circle is given by

$$C_n = 2^{n-1} \text{ for all } n \in \mathbb{Z}^+.$$

c

$n = 6$

By the conjecture we expect
 $2^{6-1} = 2^5 = 32$ regions, but there are only 31.
 So, we no longer believe the conjecture.

EXERCISE 9B.1

- 1 a** If $n = 0$, $3^n + 1 = 3^0 + 1 = 2$ which is divisible by 2.

$$\begin{aligned}
 3^n + 1 &= (1 + 2)^n + 1 \\
 &= 1^n + \binom{n}{1} 2 + \binom{n}{2} 2^2 + \binom{n}{3} 2^3 + \dots + \binom{n}{n-1} 2^{n-1} + \binom{n}{n} 2^n + 1 \\
 &= 2 + \binom{n}{1} 2 + \binom{n}{2} 2^2 + \binom{n}{3} 2^3 + \dots + \binom{n}{n-1} 2^{n-1} + \binom{n}{n} 2^n \\
 &= 2 \left(1 + \binom{n}{1} + \binom{n}{2} 2 + \binom{n}{3} 2^2 + \dots + \binom{n}{n-1} 2^{n-2} + \binom{n}{n} 2^{n-1} \right)
 \end{aligned}$$

where the contents of the brackets is an integer.

$\therefore 3^n + 1$ is divisible by 2.

- b** P_n is: $3^n + 1$ is divisible by 2 for all integers $n \geq 0$.

Proof: (By the principle of mathematical induction)

(1) If $n = 0$, $3^0 + 1 = 2 = 1 \times 2 \therefore P_0$ is true.

(2) If P_k is true, then $3^k + 1 = 2A$ where A is an integer, and $A \geq 1$.

$$\begin{aligned}
 \text{Now } 3^{k+1} + 1 &= 3^1 3^k + 1 \\
 &= 3(2A - 1) + 1 \quad \{\text{using } P_k\} \\
 &= 6A - 3 + 1 \\
 &= 6A - 2 \\
 &= 2(3A - 1) \quad \text{where } 3A - 1 \text{ is an integer as } A \in \mathbb{Z}
 \end{aligned}$$

Thus $3^{k+1} + 1$ is divisible by 2 if $3^k + 1$ is divisible by 2.

Since P_0 is true, and P_{k+1} is true whenever P_k is true,

then P_n is true for all integers $n \geq 0$ {Principle of mathematical induction}

- 2 a** If $n = 0$, $6^n - 1 = 6^0 - 1 = 0$ which is divisible by 5.

$$\begin{aligned}
 6^n - 1 &= (5 + 1)^n - 1 \\
 &= 5^n + \binom{n}{1} 5^{n-1} + \binom{n}{2} 5^{n-2} + \binom{n}{3} 5^{n-3} + \dots + \binom{n}{n-1} 5 + 1^n - 1 \\
 &= 5^n + \binom{n}{1} 5^{n-1} + \binom{n}{2} 5^{n-2} + \binom{n}{3} 5^{n-3} + \dots + \binom{n}{n-1} 5 \\
 &= 5 \left(5^{n-1} + \binom{n}{1} 5^{n-2} + \binom{n}{2} 5^{n-3} + \binom{n}{3} 5^{n-4} + \dots + \binom{n}{n-1} \right)
 \end{aligned}$$

where the contents of the brackets is an integer.

$\therefore 6^n - 1$ is divisible by 5.

- b** P_n is: $6^n - 1$ is divisible by 5 for all integers $n \geq 0$

Proof: (By the principle of mathematical induction)

(1) If $n = 0$, $6^0 - 1 = 0$ which is divisible by 5 $\therefore P_0$ is true

(2) If P_k is true, then $6^k - 1 = 5A$ where $A \in \mathbb{N}$

$$\begin{aligned}
 \text{Now } 6^{k+1} - 1 &= 6^1 6^k - 1 \\
 &= 6(5A + 1) - 1 \quad \{\text{using } P_k\} \\
 &= 30A + 6 - 1 \\
 &= 30A + 5 \\
 &= 5(6A + 1) \quad \text{where } 6A + 1 \text{ is an integer as } A \in \mathbb{N}
 \end{aligned}$$

Thus, $6^{k+1} - 1$ is divisible by 5 if $6^k - 1$ is divisible by 5.

Since P_0 is true, and P_{k+1} is true whenever P_k is true,

then P_n is true for all integers $n \geq 0$ {Principle of mathematical induction}

- 3 a** P_n is: $n^3 + 2n$ is divisible by 3 for all positive integers n

Proof: (By the principle of mathematical induction)

- (1) If $n = 1$, $1^3 + 2(1) = 3$ which is divisible by 3
 (2) If P_k is true, then $k^3 + 2k = 3A$ where $A \in \mathbb{Z}$

$$\begin{aligned} \text{Now } (k+1)^3 + 2(k+1) &= k^3 + 3k^2 + 3k + 1 + 2k + 2 \\ &= (k^3 + 2k) + 3k^2 + 3k + 3 \\ &= 3A + 3k^2 + 3k + 3 \quad \{\text{using } P_k\} \\ &= 3(A + k^2 + k + 1) \quad \text{where } A + k^2 + k + 1 \text{ is an integer} \\ &\quad \text{as } A \text{ and } k \text{ are integers} \end{aligned}$$

Thus $(k+1)^3 + 2(k+1)$ is divisible by 3 if $k^3 + 2k$ is divisible by 3.

Since P_1 is true, and P_{k+1} is true whenever P_k is true,
 then P_n is true for all positive integers n {Principle of mathematical induction}

- b** P_n is: $n(n^2 + 5)$ is divisible by 6 for all integers $n \in \mathbb{Z}^+$

Proof: (By the principle of mathematical induction)

- (1) If $n = 1$, $1(1^2 + 5) = 1 \times 6 = 6$ which is divisible by 6 $\therefore P_1$ is true
 (2) If P_k is true, then $k(k^2 + 5) = 6A$ where A is an integer

$$\begin{aligned} \text{Now } (k+1)[(k+1)^2 + 5] &= (k+1)(k^2 + 2k + 1 + 5) \\ &= (k+1)(k^2 + 2k + 6) \\ &= k^3 + 2k^2 + 6k + k^2 + 2k + 6 \\ &= k^3 + 5k + [3k^2 + 3k + 6] \\ &= k(k^2 + 5) + 3k(k+1) + 6 \\ &= 6A + 6 + 3k(k+1) \end{aligned}$$

We notice that $k(k+1)$ is the product of consecutive integers,
 one of which must be even $\therefore k(k+1) = 2B$ where $B \in \mathbb{Z}$

$$\begin{aligned} \therefore (k+1)[(k+1)^2 + 5] &= 6A + 6 + 3(2B) \\ &= 6(A + 1 + B) \quad \text{where } A + 1 + B \in \mathbb{Z} \end{aligned}$$

Thus $(k+1)[(k+1)^2 + 5]$ is divisible by 6 if $k(k^2 + 5)$ is divisible by 6.

Since P_1 is true, and P_{k+1} is true whenever P_k is true,
 then P_n is true for all integers $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

- c** P_n is: $7^n - 4^n - 3^n$ is divisible by 12 for all $n \in \mathbb{Z}^+$

Proof: (By the principle of mathematical induction)

- (1) If $n = 1$, $7^1 - 4^1 - 3^1 = 0$ which is divisible by 12 $\therefore P_1$ is true
 (2) If P_k is true, then $7^k - 4^k - 3^k = 12A$ where $A \in \mathbb{Z}$

$$\begin{aligned} \text{Now } 7^{k+1} - 4^{k+1} - 3^{k+1} &= 7(7^k) - 4(4^k) - 3(3^k) \\ &= 7[12A + 4^k + 3^k] - 4(4^k) - 3(3^k) \quad \{\text{using } P_k\} \\ &= 84A + 7(4^k) + 7(3^k) - 4(4^k) - 3(3^k) \\ &= 84A + 3(4^k) + 4(3^k) \\ &= 84A + 3 \times 4 \times 4^{k-1} + 4 \times 3 \times 3^{k-1} \\ &= 12(7A + 4^{k-1} + 3^{k-1}) \quad \text{where } k \geq 2, k \in \mathbb{Z}^+ \\ &= 12 \times \text{an integer} \quad \{\text{as } 4^{k-1} \text{ and } 3^{k-1} \text{ are integers}\} \end{aligned}$$

Thus $7^{k+1} - 4^{k+1} - 3^{k+1}$ is divisible by 12 if $7^k - 4^k - 3^k$ is divisible by 12.

Since P_1 is true, and P_{k+1} is true whenever P_k is true,
 then P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

EXERCISE 9B.2

1 a P_n is: $1 + 2 + 3 + 4 + \dots + n = \frac{n(n+1)}{2}$ for all $n \in \mathbb{Z}^+$

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, LHS = 1 and RHS = $\frac{1(2)}{2} = 1$, $\therefore P_1$ is true

(2) If P_k is true then $1 + 2 + 3 + 4 + \dots + k = \frac{k(k+1)}{2}$

Thus $1 + 2 + 3 + 4 + \dots + k + (k+1)$

$$= \frac{k(k+1)}{2} + k + 1 \quad \{\text{using } P_k\}$$

$$= \frac{k(k+1)}{2} + \frac{2(k+1)}{2} \quad \{\text{to equalise denominators}\}$$

$$= \frac{(k+1)(k+2)}{2} \quad \{\text{common factor of } \frac{(k+1)}{2}\}$$

$$= \frac{(k+1)([k+1] + 1)}{2}$$

Since P_1 is true, and P_{k+1} is true whenever P_k is true,

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, LHS = $1 \times 2 = 2$ and RHS = $\frac{1(2)(3)}{3} = 2$, $\therefore P_1$ is true

(2) If P_k is true then

$$1 \times 2 + 2 \times 3 + 3 \times 4 + \dots + k(k+1) = \frac{k(k+1)(k+2)}{3}$$

$$\therefore 1 \times 2 + 2 \times 3 + 3 \times 4 + \dots + k(k+1) + (k+1)(k+2)$$

$$= \frac{k(k+1)(k+2)}{3} + (k+1)(k+2) \quad \{\text{using } P_k\}$$

$$= \frac{k(k+1)(k+2)}{3} + \frac{3(k+1)(k+2)}{3} \quad \{\text{to equalise denominators}\}$$

$$= \frac{(k+1)(k+2)(k+3)}{3} \quad \{\text{common factor of } (k+1)(k+2)\}$$

$$= \frac{[k+1]([k+1] + 1)([k+1] + 2)}{3}$$

Since P_1 is true, and P_{k+1} is true whenever P_k is true,
then P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

c P_n is: $3 \times 5 + 6 \times 6 + 9 \times 7 + 12 \times 8 + \dots + 3n(n+4) = \frac{n(n+1)(2n+13)}{2}$
for all $n \in \mathbb{Z}^+$

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, LHS = $3 \times 5 = 15$, RHS = $\frac{1 \times 2 \times (2+13)}{2} = 15$, $\therefore P_1$ is true

(2) If P_k is true, then

$$3 \times 5 + 6 \times 6 + 9 \times 7 + \dots + 3k(k+4) = \frac{k(k+1)(2k+13)}{2}$$

$$\begin{aligned}
 \text{Now } & 3 \times 5 + 6 \times 6 + 9 \times 7 + \dots + 3k(k+4) + 3(k+1)(k+5) \\
 &= \frac{k(k+1)(2k+13)}{2} + 3(k+1)(k+5) \quad \{\text{using } P_k\} \\
 &= \frac{k(k+1)(2k+13)}{2} + \frac{6(k+1)(k+5)}{2} \quad \{\text{to equalise denominators}\} \\
 &= \frac{(k+1)[k(2k+13) + 6(k+5)]}{2} \quad \{\text{common factor}\} \\
 &= \frac{(k+1)[2k^2 + 19k + 30]}{2} \\
 &= \frac{(k+1)(k+2)(2k+15)}{2} \\
 &= \frac{(k+1)([k+1] + 1)(2[k+1] + 13)}{2}
 \end{aligned}$$

Since P_1 is true, and P_{k+1} is true whenever P_k is true,
then P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

d P_n is: $1^3 + 2^3 + 3^3 + 4^3 + \dots + n^3 = \frac{n^2(n+1)^2}{4}$ for all $n \in \mathbb{Z}^+$

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, LHS = $1^3 = 1$, RHS = $\frac{1^2(2)^2}{4} = 1 \therefore P_1$ is true

(2) If P_k is true, then $1^3 + 2^3 + 3^3 + \dots + k^3 = \frac{k^2(k+1)^2}{4}$

$$\begin{aligned}
 \text{Now } & 1^3 + 2^3 + 3^3 + \dots + k^3 + (k+1)^3 \\
 &= \frac{k^2(k+1)^2}{4} + (k+1)^3 \quad \{\text{using } P_k\} \\

 \end{aligned}$$

Since P_1 is true, and P_{k+1} is true whenever P_k is true,
then P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

- 2 a** The sum of the first n odd numbers $1 + 3 + 5 + 7 + \dots + 2n - 1$ is the sum of the first n terms of an arithmetic series.

$$u_1 = 1, d = 2. \therefore u_n = u_1 + (n-1)d = 1 + 2(n-1) = 2n - 1.$$

$$\begin{aligned}
 \text{Thus } S_n &= \frac{n}{2}(2u_1 + (n-1)d) \\
 &= \frac{n}{2}(2 \times 1 + 2(n-1)) \\
 &= \frac{n}{2}(2 + 2n - 2) \\
 &= \frac{n}{2}(2n) \\
 &= n^2
 \end{aligned}$$

So, the sum of the first n odd numbers is n^2 .

b P_n is: $1 + 3 + 5 + 7 + \dots + (2n - 1) = n^2$ for all $n \in \mathbb{Z}^+$.

&\quad + (3a + b - a\sqrt{5})(3 - \sqrt{5})^n
\end{aligned}$$

$$\text{Equating coefficients of } (3 + \sqrt{5})^n, \quad 14 + 6\sqrt{5} = 3a + b + a\sqrt{5}$$

Equating rational and irrational parts,

$$3a + b = 14 \quad \text{and} \quad a = 6$$

$$\therefore a = 6 \quad \text{and} \quad b = -4 \quad \{\text{this checks with the coefficients of } (3 - \sqrt{5})^n\}$$

$$\therefore u_{n+2} = 6u_{n+1} - 4u_n$$

P_n is: if $u_n = (3 + \sqrt{5})^n + (3 - \sqrt{5})^n$ where $n \in \mathbb{Z}^+$, then u_n is a multiple of 2^n

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, $u_1 = (3 + \sqrt{5}) + (3 - \sqrt{5})$
 $= 6$ which is a multiple of $2^1 = 2$, so P_1 is true.

If $n = 2$, $u_2 = (3 + \sqrt{5})^2 + (3 - \sqrt{5})^2$
 $= 9 + 6\sqrt{5} + 5 + 9 - 6\sqrt{5} + 5$
 $= 28$ which is a multiple of $2^2 = 4$, so P_2 is true.

(2) If P_k and P_{k+1} are true, then $u_k = A \times 2^k$, where $A \in \mathbb{Z}$
 and $u_{k+1} = B \times 2^{k+1}$, where $B \in \mathbb{Z}$

Now $u_{k+2} = 6u_{k+1} - 4u_k$ {using the above result}
 $= 6(B \times 2^{k+1}) - 4(A \times 2^k)$
 $= 3B \times 2^{k+2} - A \times 2^{k+2}$
 $= (3B - A) \times 2^{k+2}$

which is a multiple of 2^{k+2} since $3B - A \in \mathbb{Z}$ {as $A, B \in \mathbb{Z}$ }

$\therefore P_{k+2}$ is true.

Since P_1 and P_2 are true, and P_{k+2} is true whenever P_k and P_{k+1} are true, then P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

 $\therefore x^2 = \frac{25}{3}$
 $\therefore x = \pm \frac{5}{\sqrt{3}}$
 But $x > 0$, so $x = \frac{5}{\sqrt{3}}$

7 a Area = 11.6 m²

$$\therefore 11.6 = \frac{1}{2} \times 6 \times 4 \times \sin \theta$$

$$\therefore \sin \theta = \frac{29}{30}$$

$$\therefore \theta = \sin^{-1} \left(\frac{29}{30} \right)$$

$$\therefore \theta \approx 75.2^\circ$$

b Let the third side have length x m.

By the cosine rule,

$$x^2 = 6^2 + 4^2 - 2 \times 6 \times 4 \times \cos 75.2^\circ$$

$$\therefore x = \sqrt{6^2 + 4^2 - 2 \times 6 \times 4 \times \cos 75.2^\circ}$$

$$\therefore x \approx 6.30$$

The third side has length 6.30 m.

8 a $11^2 = x^2 + 8^2 - 2 \times x \times 8 \times \cos 70^\circ$

$$\therefore 121 = x^2 + 64 - 16x \cos 70^\circ$$

$$\therefore x^2 - (16 \cos 70^\circ)x - 57 = 0$$

Using the quadratic formula or technology,

$$x \approx -5.29 \text{ or } 10.8.$$

But $x > 0$, so $x \approx 10.8$.

b $13^2 = x^2 + 5^2 - 2 \times x \times 5 \times \cos 130^\circ$

$$\therefore 169 = x^2 + 25 - 10x \cos 130^\circ$$

$$\therefore x^2 - (10 \cos 130^\circ)x - 144 = 0$$

Using the quadratic formula or technology,

$$x \approx -15.6 \text{ or } 9.21.$$

But $x > 0$, so $x \approx 9.21$.

9 $5^2 = x^2 + 6^2 - 2 \times x \times 6 \times \cos 40^\circ$

$$\therefore 25 = x^2 + 36 - 12x \cos 40^\circ$$

$$\therefore x^2 - (12 \cos 40^\circ)x + 11 = 0$$

Using the quadratic formula or technology, $x \approx 1.41$ or 7.78 .

10 a $(3x + 1)^2 = (x + 2)^2 + (x + 3)^2 - 2(x + 2)(x + 3) \cos \theta$

$$\therefore 9x^2 + 6x + 1 = x^2 + 4x + 4 + x^2 + 6x + 9 - 2(x^2 + 5x + 6)\left(-\frac{1}{5}\right)$$

$$\therefore 9x^2 + 6x + 1 = 2x^2 + 10x + 13 + \frac{2}{5}x^2 + 2x + \frac{12}{5}$$

$$\therefore \frac{33}{5}x^2 - 6x - \frac{72}{5} = 0$$

$$\therefore 33x^2 - 30x - 72 = 0$$

$$\therefore 3(11x + 12)(x - 2) = 0$$

$$\therefore x = -\frac{12}{11} \text{ or } 2$$

But $3x + 1 > 0$, so $x = 2$

b $\cos^2 \theta + \sin^2 \theta = 1$

$$\therefore \frac{1}{25} + \sin^2 \theta = 1$$

$$\therefore \sin^2 \theta = \frac{24}{25}$$

$$\therefore \sin \theta = \pm \frac{\sqrt{24}}{5}$$

But $0^\circ < \theta < 180^\circ$, so $\sin \theta > 0$

$$\therefore \sin \theta = \frac{\sqrt{24}}{5}$$

$$\therefore \text{area} = \frac{1}{2} \times (x + 2) \times (x + 3) \times \sin \theta$$

$$= \frac{1}{2} \times 4 \times 5 \times \frac{\sqrt{24}}{5}$$

$$= 2\sqrt{24}$$

$$= 4\sqrt{6} \text{ cm}^2$$

11

$$\cos \theta = \frac{4^2 + 3^2 - 6^2}{2 \times 3 \times 4}$$

$$\therefore \theta = \cos^{-1} \left(\frac{16 + 9 - 36}{24} \right)$$

$$= \cos^{-1} \left(-\frac{11}{24} \right)$$

$$\approx 117.3^\circ$$

$$\cos \phi = \frac{3^2 + 6^2 - 4^2}{2 \times 3 \times 6}$$

$$\therefore \phi = \cos^{-1} \left(\frac{9 + 36 - 16}{36} \right)$$

$$= \cos^{-1} \left(\frac{29}{36} \right)$$

$$\approx 36.3^\circ$$

$$\therefore 180^\circ - \theta \approx 180^\circ - 117.3^\circ \approx 62.7^\circ \quad \text{and} \quad 180^\circ - \phi \approx 180^\circ - 36.3^\circ \approx 143.7^\circ$$

So, the angles are 36.3° , 62.7° , 117.3° , and 143.7° .

EXERCISE 11C.1

1 a By the sine rule,

$$\frac{x}{\sin 48^\circ} = \frac{23}{\sin 37^\circ}$$

$$\therefore x = \frac{23 \times \sin 48^\circ}{\sin 37^\circ}$$

$$\therefore x \approx 28.4$$

b By the sine rule,

$$\frac{x}{\sin 115^\circ} = \frac{11}{\sin 48^\circ}$$

$$\therefore x = \frac{11 \times \sin 115^\circ}{\sin 48^\circ}$$

$$\therefore x \approx 13.4$$

c By the sine rule,

$$\frac{x}{\sin 51^\circ} = \frac{4.8}{\sin 80^\circ}$$

$$\therefore x = \frac{4.8 \times \sin 51^\circ}{\sin 80^\circ}$$

$$\therefore x \approx 3.79$$

2 a

By the sine rule, $\frac{a}{\sin 63^\circ} = \frac{18}{\sin 49^\circ}$

$$\therefore a = \frac{18 \times \sin 63^\circ}{\sin 49^\circ}$$

$$\therefore a \approx 21.3 \text{ cm}$$

b

By the sine rule, $\frac{b}{\sin 73^\circ} = \frac{34}{\sin 25^\circ}$

$$\therefore b = \frac{34 \times \sin 73^\circ}{\sin 25^\circ}$$

$$\therefore b \approx 76.9 \text{ cm}$$

c

By the sine rule, $\frac{c}{\sin 48^\circ} = \frac{6.4}{\sin 111^\circ}$

$$\therefore c = \frac{6.4 \times \sin 48^\circ}{\sin 111^\circ}$$

$$\therefore c \approx 5.09 \text{ cm}$$

EXERCISE 11C.2

1 By the sine rule, $\frac{\sin C}{11} = \frac{\sin 40^\circ}{8}$

$$\therefore \sin C = \frac{11 \times \sin 40^\circ}{8}$$

$$\therefore C = \sin^{-1} \left(\frac{11 \times \sin 40^\circ}{8} \right) \text{ or its supplement}$$

$$\therefore C \approx 62.1^\circ \text{ or } (180 - 62.1)^\circ$$

$$\therefore C \approx 62.1^\circ \text{ or } 117.9^\circ$$

2 a $\frac{\sin \hat{BAC}}{a} = \frac{\sin \hat{ABC}}{b}$

$$\therefore \sin \hat{BAC} = \frac{14.6 \times \sin 65^\circ}{17.4}$$

$$\therefore \hat{BAC} = \sin^{-1} \left(\frac{14.6 \times \sin 65^\circ}{17.4} \right)$$

or its supplement

$$\therefore \hat{BAC} \approx 49.5^\circ \text{ or } 180^\circ - 49.5^\circ$$

$$\therefore \hat{BAC} \approx 49.5^\circ \text{ or } 130.5^\circ$$

Check: $\hat{BAC} = 130.5^\circ$ is impossible as $\hat{BAC} + \hat{ABC} = 130.5^\circ + 65^\circ$ is already over 180° . $\therefore \hat{BAC} \approx 49.5^\circ$

b $\frac{\sin \hat{ABC}}{43.8} = \frac{\sin 43^\circ}{31.4}$

$$\therefore \sin \hat{ABC} = \frac{43.8 \times \sin 43^\circ}{31.4}$$

$$\therefore \hat{ABC} = \sin^{-1} \left(\frac{43.8 \times \sin 43^\circ}{31.4} \right)$$

or its supplement

$$\therefore \hat{ABC} \approx 72.0^\circ \text{ or } 108^\circ$$

both of which are possible as $108 + 43 = 151$ which is < 180 .

$$\frac{\sin \hat{ACB}}{4.8} = \frac{\sin 71^\circ}{6.5}$$

$$\therefore \sin \hat{ACB} = \frac{4.8 \times \sin 71^\circ}{6.5}$$

$$\therefore \hat{ACB} = \sin^{-1} \left(\frac{4.8 \times \sin 71^\circ}{6.5} \right) \text{ or its supplement}$$

$$\therefore \hat{ACB} \approx 44.3^\circ \text{ or } 135.7^\circ$$

But $135.7 + 71 > 180$, so this case is impossible. $\therefore \hat{ACB} \approx 44.3^\circ$

3 The third angle is $180^\circ - 85^\circ - 68^\circ = 27^\circ$

$$\text{Now } \frac{\sin 85^\circ}{11.4} \approx 0.08738 \text{ and } \frac{\sin 27^\circ}{9.8} \approx 0.04632$$

This is not possible since $\frac{\sin 85^\circ}{11.4} \neq \frac{\sin 27^\circ}{9.8}$ violates the sine rule.

4

In $\triangle ABD$,
 $\theta = 78 - 12$
 $\therefore \hat{ABC} = 66^\circ$

$$\begin{aligned} \text{Now } \frac{x}{\sin 12^\circ} &= \frac{20}{\sin 66^\circ} \\ \therefore x &= \frac{20 \times \sin 12^\circ}{\sin 66^\circ} \\ \therefore x &\approx 4.55 \\ \therefore BD &\approx 4.55 \text{ cm} \end{aligned}$$

5 First we find the length of the diagonal, d m.

$$\begin{aligned} \frac{d}{\sin 118^\circ} &= \frac{22}{\sin 30^\circ} \\ \therefore d &= \frac{22 \times \sin 118^\circ}{\sin 30^\circ} \\ \therefore d &\approx 38.85 \end{aligned}$$

$$\text{Now } \theta = 180 - 30 - 118 = 32$$

$$\therefore \hat{ACD} = 90^\circ - 32^\circ = 58^\circ$$

$$\begin{aligned} \text{Using the sine rule, } \frac{y}{\sin 58^\circ} &= \frac{38.85}{\sin 95^\circ} \quad \text{and} \quad \frac{x}{\sin(180 - 95 - 58)^\circ} \approx \frac{38.85}{\sin 95^\circ} \\ \therefore y &\approx \frac{38.85 \times \sin 58^\circ}{\sin 95^\circ} & \therefore x &\approx \frac{38.85 \times \sin 27^\circ}{\sin 95^\circ} \\ \therefore y &\approx 33.1 & \therefore x &\approx 17.7 \end{aligned}$$

6

$$\begin{aligned} \frac{\sin \hat{B}}{8} &= \frac{\sin 58^\circ}{6.84} \\ \therefore \sin \hat{B} &= \frac{8 \sin 58^\circ}{6.84} \\ \therefore \hat{B} &= \sin^{-1} \left(\frac{8 \sin 58^\circ}{6.84} \right) \text{ or its supplement} \\ \therefore \hat{B} &\approx 83^\circ \text{ or } (180 - 83)^\circ \\ \therefore \hat{B} &\approx 83^\circ \text{ or } 97^\circ \end{aligned}$$

$$\begin{aligned} \text{b } \cos \hat{B} &= \frac{5.1^2 + 6.84^2 - 8^2}{2 \times 5.1 \times 6.84} \\ \therefore \hat{B} &= \cos^{-1} \left(\frac{5.1^2 + 6.84^2 - 8^2}{2 \times 5.1 \times 6.84} \right) \\ \therefore \hat{B} &\approx 83^\circ \end{aligned}$$

c When faced with using either the sine rule or the cosine rule, it is better to use the cosine rule as it avoids the ambiguous case.

7 $9^2 = x^2 + 7^2 - 2 \times x \times 7 \times \cos 30^\circ$

$$\therefore 81 = x^2 + 49 - 14x\left(\frac{\sqrt{3}}{2}\right)$$

$$\therefore x^2 - \frac{14\sqrt{3}}{2}x - 32 = 0$$

Using the quadratic formula or technology,

$$x \approx -2.23 \text{ or } 14.35$$

but $x > 0$, so $x \approx 14.35$

$$\begin{aligned} \therefore \text{area of triangle} &\approx \frac{1}{2} \times 7 \times 14.35 \times \sin 30^\circ \\ &\approx 25.1 \text{ cm}^2 \end{aligned}$$

8

$$\begin{aligned} \widehat{ABC} &= 180^\circ - 47^\circ \\ &= 133^\circ \end{aligned}$$

$$\cos 133^\circ = \frac{67^2 + 35^2 - AC^2}{2 \times 67 \times 35} \quad \{\text{cosine rule}\}$$

$$AC^2 = 5714 - 4690 \cos 133^\circ$$

$$AC = 94.41 \text{ mm} \quad \{\text{as } AC > 0\}$$

$$\frac{\sin 133^\circ}{94.41} = \frac{\sin \widehat{BAC}}{35}$$

$$\begin{aligned} \widehat{BAC} &= \sin^{-1} \left(\frac{35 \sin 133^\circ}{94.41} \right) \\ &\approx 15.7^\circ \end{aligned}$$

9

$$\frac{2x-5}{\sin 45^\circ} = \frac{x+3}{\sin 30^\circ}$$

$$\therefore (2x-5) \sin 30^\circ = (x+3) \sin 45^\circ$$

$$\therefore \frac{2x-5}{2} = \frac{x+3}{\sqrt{2}}$$

$$\therefore 2\sqrt{2}x - 5\sqrt{2} = 2x + 6$$

$$\therefore -6 - 5\sqrt{2} = x(2 - 2\sqrt{2})$$

$$\begin{aligned} \therefore x &= \left(\frac{-6 - 5\sqrt{2}}{2 - 2\sqrt{2}} \right) \left(\frac{2 + 2\sqrt{2}}{2 + 2\sqrt{2}} \right) \\ &= \frac{-12 - 12\sqrt{2} - 10\sqrt{2} - 10(2)}{4 - 4(2)} \\ &= \frac{-32 - 22\sqrt{2}}{-4} \\ &= 8 + \frac{11}{2}\sqrt{2} \end{aligned}$$

EXERCISE 11D

1

$$\theta^\circ + 28^\circ = 53^\circ$$

{exterior angle of a $\triangle$ theorem}

$$\therefore \theta = 25$$

By the sine rule,

$$\frac{x}{\sin 28^\circ} = \frac{20}{\sin 25^\circ}$$

$$\therefore x \approx \frac{20 \times \sin 28^\circ}{\sin 25^\circ}$$

$$\therefore x \approx 22.22$$

$$\text{and } \sin 53^\circ = \frac{h}{x}$$

$$\therefore h = x \sin 53^\circ$$

$$\approx 22.22 \times \sin 53^\circ$$

$$\approx 17.7 \text{ m}$$

$\therefore$ the pole is 17.7 m high.

2

$$PR^2 = 63^2 + 175^2 - 2 \times 63 \times 175 \times \cos 112^\circ$$

$$\therefore PR = \sqrt{63^2 + 175^2 - 2 \times 63 \times 175 \times \cos 112^\circ}$$

$$\therefore PR \approx 207 \text{ m}$$

$$3 \quad \cos T = \frac{220^2 + 340^2 - 165^2}{2 \times 220 \times 340}$$

$$\therefore T = \cos^{-1} \left(\frac{136\,775}{149\,600} \right)$$

$$\therefore T \approx 23.9$$

$\therefore$ the tee shot was 23.9° off line.

4

 In $\triangle ABD$,

$$\cos(23.6 + 15.9)^\circ = \frac{200}{x}$$

$$\therefore x = \frac{200}{\cos 39.5^\circ}$$

$$\therefore x \approx 259.2$$

 In $\triangle ACD$,

$$\frac{h}{\sin 15.9^\circ} = \frac{x}{\sin 113.6^\circ}$$

$$\therefore h \approx \frac{259.2 \times \sin 15.9^\circ}{\sin 113.6^\circ}$$

$$\therefore h \approx 77.5$$

$$\therefore \text{the tower is } 77.5 \text{ m high.}$$

5

a

$$\alpha = 140^\circ \quad \{\text{co-interior angles}\}$$

$$\therefore \widehat{PXC} = 360^\circ - 140^\circ - 155^\circ \quad \{\text{angles at a point}\}$$

$$= 65^\circ$$

$$\text{So, } PC^2 = 4^2 + 6^2 - 2 \times 4 \times 6 \cos 65^\circ$$

$$\therefore PC = \sqrt{16 + 36 - 48 \cos 65^\circ}$$

$$\approx 5.6315 \text{ km}$$

 $\therefore$ Esko hikes 5.63 km.

b

$$\cos \theta \approx \frac{4^2 + 5.6315^2 - 6^2}{2 \times 4 \times 5.6315}$$

$$\therefore \theta \approx 74.9^\circ$$

$$\therefore \text{bearing} = 40^\circ + \theta$$

$$\approx 114.9^\circ$$

 $\therefore$ Esko hikes on a bearing of 115° .

$$\text{c i} \quad \text{speed} = \frac{\text{distance}}{\text{time}} \Rightarrow \text{time} = \frac{\text{distance}}{\text{speed}}$$

$$\therefore \text{time}_{\text{Ritva}} = \frac{4 + 6}{10} = 1 \text{ hour} \quad \text{and} \quad \text{time}_{\text{Esko}} \approx \frac{5.6315}{6} \approx 0.9386 \text{ hours}$$

$$\approx 56.32 \text{ min}$$

So Esko arrives at the campsite first.

$$\text{ii} \quad 60 - 56.32 = 3.68$$

Esko needs to wait about 3.68 minutes before Ritva arrives.

$$\text{d} \quad \phi \approx 180^\circ - 114.9^\circ \approx 65.1^\circ \quad \{\text{co-interior angles}\}$$

$$\therefore 360^\circ - \phi \approx 295^\circ$$

 The return bearing is 295° .

6

$$\cos \theta = \frac{23^2 + 26^2 - 5^2}{2 \times 23 \times 26}$$

$$\therefore \theta = \cos^{-1} \left(\frac{1180}{1196} \right)$$

$$\therefore \theta \approx 9.38^\circ$$

 $\therefore$ the angle of view is 9.38° .

7

 In $\triangle ABD$,

$$\frac{AD}{\sin 98.3^\circ} = \frac{42}{\sin 4.9^\circ}$$

$$\therefore AD = \frac{42 \times \sin 98.3^\circ}{\sin 4.9^\circ}$$

$$\therefore AD \approx 486.56 \text{ m}$$

 In $\triangle ADC$,

$$\sin 13.2^\circ = \frac{h + 42}{AD}$$

$$\therefore h + 42 \approx 486.56 \times \sin 13.2^\circ$$

$$\therefore h + 42 \approx 111.1$$

$$\therefore h \approx 69.1$$

$$\therefore \text{the hill is } 69.1 \text{ m high.}$$

$$\theta = 13.2^\circ - 8.3^\circ = 4.9^\circ$$

8

By the sine rule, $\frac{a}{\sin 40^\circ} = \frac{150}{\sin 72^\circ}$
 $\therefore a = \frac{150 \times \sin 40^\circ}{\sin 72^\circ}$
 $\therefore a \approx 101.38$

a $\sin 22^\circ \approx \frac{x}{101.38}$
 $\therefore x \approx 101.38 \times \sin 22^\circ$
 $\therefore x \approx 38.0$
 $\therefore$ the tree is 38.0 m high.

b $\cos 22^\circ \approx \frac{y}{101.38}$
 $\therefore y \approx 101.38 \times \cos 22^\circ$
 $\therefore y \approx 94.0$
 $\therefore$ the tree is 94.0 m from the building.

9 Using Pythagoras' theorem

$RQ = \sqrt{4^2 + 7^2} = \sqrt{65}$ cm
 $PQ = \sqrt{8^2 + 7^2} = \sqrt{113}$ cm
 $PR = \sqrt{8^2 + 4^2} = \sqrt{80}$ cm

Now $\cos \widehat{PQR} = \frac{(\sqrt{113})^2 + (\sqrt{65})^2 - (\sqrt{80})^2}{2 \times \sqrt{113} \times \sqrt{65}}$
 $\therefore \cos \widehat{PQR} \approx \left(\frac{98}{171.4}\right)$
 $\therefore \widehat{PQR} \approx \cos^{-1}\left(\frac{98}{171.4}\right)$
 $\therefore \widehat{PQR} \approx 55.1$ So, $\widehat{PQR}$ measures 55.1° .

10

$\frac{x}{\sin 67^\circ} = \frac{12}{\sin 71^\circ} = \frac{y}{\sin 42^\circ}$
 $\therefore x = \frac{12 \times \sin 67^\circ}{\sin 71^\circ}$ and $y = \frac{12 \times \sin 42^\circ}{\sin 71^\circ}$
 $\therefore x \approx 11.7$ $\therefore y \approx 8.49$
 So, C is 11.7 km from A and 8.49 km from B.

11

a $QS = \sqrt{8^2 + 12^2 - 2 \times 8 \times 12 \times \cos 70^\circ}$
 ≈ 11.93
 $\therefore \text{area} \approx \frac{1}{2} \times 8 \times 12 \times \sin 70^\circ + \frac{1}{2} \times 10 \times 11.93 \times \sin 30^\circ$
 $\approx 74.9 \text{ km}^2$

b 1 ha is $100 \text{ m} \times 100 \text{ m}$
 $= 0.1 \text{ km} \times 0.1 \text{ km}$
 $= 0.01 \text{ km}^2$
 $\therefore 1 \text{ km}^2 = 100 \text{ ha}$
 $\therefore \text{area} \approx 7490 \text{ ha}$

12

Distance = speed $\times$ time
 So, after 45 min = 0.75 h, $AT = 6 \times 0.75 = 4.5 \text{ km}$
 $AP = 8 \times 0.75 = 6 \text{ km}$
 Now $PT = \sqrt{4.5^2 + 6^2 - 2 \times 4.5 \times 6 \times \cos 120^\circ}$
 $\therefore PT \approx 9.12$
 So, they are 9.12 km apart.

13

In $\triangle ABC$, $\frac{AC}{\sin 110^\circ} = \frac{200}{\sin 38^\circ}$
 $\therefore AC = \frac{200 \times \sin 110^\circ}{\sin 38^\circ} \approx 305.26$
 and in $\triangle ACD$, $\frac{x}{\sin 8^\circ} \approx \frac{305.26}{\sin 30^\circ}$
 $\therefore x \approx \frac{305.26 \times \sin 8^\circ}{\sin 30^\circ} \approx 84.968$
 $\therefore$ the metal strip is 85.0 mm wide.

14

$$x = \sqrt{6^2 + (4.5)^2 - 2 \times 6 \times 4.5 \times \cos 148^\circ}$$

$$\therefore x \approx 10.1$$

$$\therefore \text{the orienteer is 10.1 km from the start.}$$

15

$$\text{In } \triangle PST, \tan 25^\circ = \frac{h}{x} \quad \text{In } \triangle PMT, \tan 15^\circ = \frac{h}{y}$$

$$\therefore x = \frac{h}{\tan 25^\circ} \approx 2.145h \quad \therefore y = \frac{h}{\tan 15^\circ} \approx 3.732h$$

$$\text{But } \widehat{STM} = 65^\circ \quad \{\text{equal alternate angles}\}$$

$$\text{and } 100^2 = x^2 + y^2 - 2xy \cos 65^\circ$$

$$\therefore 10\,000 \approx (2.145h)^2 + (3.732h)^2 - 2 \times (2.145)(3.732)h^2 \cos 65^\circ$$

$$\therefore 10\,000 \approx 11.762h^2$$

$$\therefore h^2 \approx 850.17$$

$$\therefore h \approx 29.2 \quad \text{So, the tree is 29.2 m high.}$$

16

$$\text{By the cosine rule}$$

$$x^2 = 23.8^2 + 31.9^2 - 2 \times 23.8 \times 31.9 \times \cos 83.6^\circ$$

$$\therefore x = \sqrt{23.8^2 + 31.9^2 - 2 \times 23.8 \times 31.9 \times \cos 83.6^\circ}$$

$$\therefore x \approx 37.6$$

$$\therefore \text{B and C are 37.6 km apart.}$$

REVIEW SET 11A

$$1 \quad \text{area} = \frac{1}{2} \times 7 \times 8 \times \sin 30^\circ$$

$$= 28 \times \frac{1}{2}$$

$$= 14 \text{ km}^2$$

2 If the unknown is an angle, use the cosine rule to avoid the ambiguous case.

$$3 \quad \text{a} \quad \text{By the cosine rule, } 7^2 = 8^2 + x^2 - 2 \times 8 \times x \times \cos 60^\circ$$

$$\therefore 49 = 64 + x^2 - 16x \left(\frac{1}{2}\right)$$

$$\therefore 49 = 64 + x^2 - 8x$$

$$\therefore x^2 - 8x + 15 = 0$$

$$\therefore (x - 3)(x - 5) = 0$$

Using $\triangle ADC$,

$$z^2 = x^2 + y^2 - 2xy \cos \theta \quad \dots (1)$$

Using $\triangle ABC$,

$$z^2 = x^2 + y^2 - 2xy \cos \phi \quad \dots (2)$$

Equating (1) and (2),

$$\cos \theta = \cos \phi$$

and since $0 < \theta, \phi < 180$,

$$\theta = \phi$$

$$\therefore \widehat{ADC} = \widehat{ABC}$$

b

Using $\triangle BAC$,

$$\frac{\sin \phi}{x} = \frac{\sin \alpha}{z} \quad \dots (2)$$

$$\{\widehat{ADC} = \widehat{ABC} \text{ from a}\}$$

Equating (1) and (2),

$$\sin \theta = \sin \phi$$

$$\therefore \theta = \phi \text{ or } \theta = 180 - \phi$$

$$\text{but } \widehat{DAB} = \theta + \phi < 180^\circ$$

$$\therefore \theta = \phi$$

$$\therefore \widehat{DAC} = \widehat{BAC}$$

6 Total distance travelled = $x + 10$ km

$$\therefore x^2 + 12x + 36 = x^2 + 100 - 20x(-\frac{1}{2})$$

$$\therefore 12x + 36 = 100 + 10x$$

$$\therefore 2x = 64$$

$$\therefore x = 32$$

$$= \frac{49}{2} \left(\frac{13\pi}{18} - \sin\left(\frac{13\pi}{18}\right) \right)$$

8 a $d^2 = x^2 + 5^2 - 2 \times x \times 5 \times \cos 20^\circ$

$$\therefore d^2 = x^2 - (10 \cos 20^\circ)x + 25$$

b d^2 is minimised when $x = \frac{-b}{2a}$

$$\therefore x = \frac{10 \cos 20^\circ}{2}$$

$$\therefore x = 5 \cos 20^\circ$$

$$\therefore d \text{ is minimised when } x = 5 \cos 20^\circ$$

c If $\widehat{BCA}$ is a right angle, then we have

$$\text{Now } \cos 20^\circ = \frac{x}{5}$$

$$\therefore x = 5 \cos 20^\circ$$

and from b, d is minimised when $x = 5 \cos 20^\circ$

$\therefore d$ is minimised when $\widehat{BCA}$ is a right angle.

9 a $y = -x^2 + 12x - 20$ has $a = -1 < 0$

$\therefore$ its shape is , and y is maximised when $x = \frac{-b}{2a} = \frac{-12}{-2} = 6$.

$$\text{When } x = 6, y = -6^2 + 12(6) - 20 = -36 + 72 - 20 = 16$$

$\therefore$ the maximum value of $y = -x^2 + 12x - 20$ is 16, which occurs when $x = 6$.

- b** **i** The perimeter is 20
 $\therefore x + y + 8 = 20$
 $\therefore y = 12 - x$
- iii** Since $y = 12 - x$, $(12 - x)^2 = x^2 + 64 - 16x \cos \theta$
 $\therefore 144 - 24x + x^2 = x^2 + 64 - 16x \cos \theta$
 $\therefore 16x \cos \theta = 24x - 80$
 $\therefore \cos \theta = \frac{24x - 80}{16x}$
 $= \frac{3x - 10}{2x}$
- c** Area $A = \frac{1}{2} \times x \times 8 \times \sin \theta$
 $= 4x \sin \theta$
 $\therefore A^2 = 16x^2 \sin^2 \theta$
 $= 16x^2 (1 - \cos^2 \theta)$
 $= 16x^2 \left[1 - \left(\frac{3x - 10}{2x} \right)^2 \right]$
 $= 16x^2 \left[1 - \frac{9x^2 - 60x + 100}{4x^2} \right]$
 $= 16x^2 - 4(9x^2 - 60x + 100)$
 $= 16x^2 - 36x^2 + 240x - 400$
 $= -20x^2 + 240x - 400$
 $= 20(-x^2 + 12x - 20)$
- d** A is maximised when A^2 is maximised since $A > 0$.
From **a**, $-x^2 + 12x - 20$ has a maximum value of 16 when $x = 6$.
When $x = 6$, $A^2 = 20(16)$
 $= 320$
 $\therefore A = \sqrt{320} \quad \{A > 0\}$
 $= 8\sqrt{5}$
Also, when $x = 6$, $y = 12 - 6$
 $= 6$
 $\therefore$ the maximum area of the triangle is $8\sqrt{5}$ units², and the triangle is isosceles when this occurs.

distance = speed $\times$ time

So, in 45 minutes, $140 \times \frac{3}{4} = 105 \text{ km}$ is travelled.
 {45 minutes = $\frac{3}{4}$ hour}

In 40 minutes, $180 \times \frac{2}{3} = 120 \text{ km}$ is travelled.
 {40 minutes = $\frac{2}{3}$ hour}

We notice that $\theta + 43 + 32 = 180$ {co-interior angles add to 180° }

Month, t	1	2	3	4	5	6	7	8	9	10	11	12
Temp, T	15	14	15	18	21	25	27	26	24	20	18	16

The period is 12 months so $\frac{2\pi}{b} = 12$
 $\therefore b = \frac{\pi}{6}$ {assuming $b > 0$ }.

Amplitude, $a \approx \frac{\text{max.} - \text{min.}}{2}$
 $\approx \frac{27 - 14}{2} \approx 6.5$

As the principal axis is midway between min. and max., then $d \approx \frac{27 + 14}{2} \approx 20.5$

When T is 20.5 (midway between min. and max.), $c \approx \frac{2 + 7}{2} \approx 4.5$ {average of t values}

$\therefore T \approx 6.5 \sin(\frac{\pi}{6}(t - 4.5)) + 20.5$ where $\frac{\pi}{6} \approx 0.524$

- b

Using technology, $T \approx 6.14 \sin(0.575t - 2.70) + 20.4$
 $\therefore T \approx 6.14 \sin(0.575(t - 4.70)) + 20.4$

The model fits reasonably well.

Month, t	1	2	3	4	5	6	7	8	9	10	11	12
Temp, T	15	16	$14\frac{1}{2}$	12	10	$7\frac{1}{2}$	7	$7\frac{1}{2}$	$8\frac{1}{2}$	$10\frac{1}{2}$	$12\frac{1}{2}$	14

The period is $\frac{2\pi}{b} = 12 \therefore b = \frac{\pi}{6}$ { $b > 0$ }

Amplitude, $a \approx \frac{\text{max.} - \text{min.}}{2} \approx \frac{16 - 7}{2} \approx 4.5$

As the principal axis is midway between min. and max. then $d \approx \frac{16 + 7}{2} \approx 11.5$

At min., $t = 7$ and at max., $t = 2 + 12 = 14 \quad \therefore \quad c \approx \frac{7 + 14}{2} \approx 10.5$

So, $T \approx 4.5 \sin(\frac{\pi}{6}(t - 10.5)) + 11.5$

b Using technology, $T \approx 4.29 \sin(0.533t + 0.769) + 11.2$ **Note:** (1) $\frac{\pi}{6} \approx 0.524 \quad \checkmark$
 $\therefore T \approx 4.29 \sin(0.533(t + 1.44)) + 11.2$ (2) $1.44 - (-10.5)$
 $\hspace{15em} = 11.94 \approx 12$

3 a For the model $H = a \sin(b(t - c)) + d$

period = $\frac{2\pi}{b} = 12.4$ hours $\therefore b = \frac{2\pi}{12.4} \approx 0.507$

We let the principal axis be 0, so $d = 0$
 $\therefore$ the amplitude $a = 7$, so the min. is -7 , and the max. is $+7$
Let $t = 0$ correspond to ‘low tide’ $\therefore t = 6.2$ corresponds to ‘high tide’

$\therefore c = \frac{0 + 6.2}{2} = 3.1$

So, $H \approx 7 \sin(0.507(t - 3.1)) + 0$
 $\therefore H \approx 7 \sin(0.507(t - 3.1))$

4 a

Month, t	1	2	3	4	5	6	7	8	9	10	11	12
Temp, T	0	0	-4	-9	-14	-17	-18	-19	-17	-13	-6	-2

The period is $\frac{2\pi}{b} = 12 \quad \therefore \quad b = \frac{\pi}{6} \quad \{b > 0\}$

Amplitude, $a \approx \frac{\text{max.} - \text{min.}}{2} \approx \frac{0 - (-19)}{2} \approx 9.5$

$d \approx \frac{\text{max.} + \text{min.}}{2} \approx \frac{0 + (-19)}{2} \approx -9.5$

At min., $t = 8$ and at max., $t = 1 + 12 = 13 \quad \therefore \quad c \approx \frac{8 + 13}{2} \approx 10.5$

So, $T \approx 9.5 \sin(\frac{\pi}{6}(t - 10.5)) - 9.5$

b The model is reasonably appropriate.

$$c = \frac{0 + 50}{2} = 25 \quad \{\text{values of } t \text{ at min. and max.}\} \quad \therefore \quad H = 10 \sin\left(\frac{\pi}{50}(t - 25)\right) + 12$$

 c controls the horizontal translation. d controls the vertical translation.

4 **a** If $y = a \cos(b(x - c)) + d$, then $a = 2$, $\pi = \frac{2\pi}{b} \therefore b = 2$
 c and d are 0 as there is no horizontal or vertical shift. $\therefore y = 2 \cos(2x)$

b If $y = a \cos(b(x - c)) + d$, then $a = 1$, $4\pi = \frac{2\pi}{b} \therefore b = \frac{1}{2}$
 A vertical shift of 2 units, no horizontal shift $\therefore d = 2$, $c = 0$.
 So, $y = \cos\left(\frac{1}{2}x\right) + 2$ or $y = \cos\left(\frac{x}{2}\right) + 2$.

c If $y = a \cos(b(x - c)) + d$, then $a = -5$, $6 = \frac{2\pi}{b} \therefore b = \frac{\pi}{3}$
 $c = d = 0$ {as there is no translation} $\therefore y = -5 \cos\left(\frac{\pi}{3}x\right)$

principal axis is $y = \frac{-5 + (-79)}{2} = -42$, so $c = -42$

Now, we see that the temperature is -68°C and rising on days 600 and 1300, so we estimate the period to be 700 days.

$$\therefore b \approx \frac{2\pi}{700} \approx 0.00898$$

$$\text{So, } T \approx 37 \sin(0.00898n) - 42^\circ\text{C}$$

c A Mars year is equivalent to one period of the temperature pattern, so 1 Mars year ≈ 700 Mars days.

$$\text{and max} = -3 + 5 = 2$$

b $y = \frac{1}{3} \cos x + 1$ has $a = \frac{1}{3}$, $c = 1$

a $T = a \sin b(t - c) + d$ period $= \frac{2\pi}{b} = 12, \therefore b = \frac{2\pi}{12} = \frac{\pi}{6}$

max. = 31.8 $\therefore a = \frac{\text{max.} - \text{min.}}{2} \approx \frac{31.8 - 17.7}{2} \approx 7.05$
min. = 17.7

$d = \frac{\text{max.} + \text{min.}}{2} \approx \frac{31.8 + 17.7}{2} \approx 24.75$

$c = \frac{7 + 14}{2} = 10.5$ {values of t at min. and max.}

So, $T \approx 7.05 \sin\left(\frac{\pi}{6}(t - 10.5)\right) + 24.75$

EXERCISE 13B

- 1 a** $H(t) = 10 \sin\left(\frac{\pi}{50}(t - 25)\right) + 12$ metres
 After 50 seconds, $t = 50$ and $H(50) = 10 \sin\left(\frac{\pi}{50}(50 - 25)\right) + 12 = 22$ metres.
 So, the green light will be 22 metres high.
- b** A full circle is completed in one period.
 $\text{period} = \frac{2\pi}{\frac{\pi}{50}} = 2\pi \times \frac{50}{\pi} = 100$ seconds
 So, it takes 100 seconds for the wheel to complete a full circle.
- c** We need to solve $H(t) = 16$ so $10 \sin\left(\frac{\pi}{50}(t - 25)\right) + 12 = 16$.
 3 minutes = $3 \times 60 = 180$ seconds
 Using technology to find the intersection points of $Y_1 = 10 \sin\left(\frac{\pi}{50}(t - 25)\right) + 12$ and $Y_2 = 16$
 for $0 \leq t \leq 180$, $t \approx 31.5, 68.5, 132, 168$
 So, in the first three minutes, the green light is 16 metres above the ground at 31.5, 68.5, 132, and 168 seconds.
- 2 a** $P(t) = 7500 + 3000 \sin\left(\frac{\pi t}{8}\right)$, $0 \leq t \leq 12$
- i** $P(0) = 7500 + 3000 \sin 0$
 $= 7500 + 0$
 $= 7500$ grasshoppers
- ii** $P(5) = 7500 + 3000 \sin\left(\frac{5\pi}{8}\right)$
 $\approx 10\,271.63$
 $\approx 10\,300$ grasshoppers
- b** The greatest value of $P(t)$ occurs when $\sin\left(\frac{\pi t}{8}\right) = 1$, so the greatest population is $7500 + 3000 = 10\,500$ grasshoppers.

The point on the unit circle with sine 1 corresponds to angle $\frac{\pi}{2}$.

$$0 \leq t \leq 12 \quad \therefore \quad 0 \leq \frac{\pi t}{8} \leq \frac{3\pi}{2}$$

$$\text{So } \frac{\pi t}{8} = \frac{\pi}{2}$$

$$\therefore t = 4$$

So the greatest population occurs after 4 weeks.

- c i** When $P(t) = 9000$,
 $7500 + 3000 \sin\left(\frac{\pi t}{8}\right) = 9000$
 $\therefore 3000 \sin\left(\frac{\pi t}{8}\right) = 1500$
 $\therefore \sin\left(\frac{\pi t}{8}\right) = \frac{1}{2}$

The points on the unit circle with sine $\frac{1}{2}$ correspond to angles $\frac{\pi}{6}$ and $\frac{5\pi}{6}$.

$$0 \leq t \leq 12 \quad \therefore \quad 0 \leq \frac{\pi t}{8} \leq \frac{3\pi}{2}$$

$$\text{So } \frac{\pi t}{8} = \frac{\pi}{6}, \frac{5\pi}{6}$$

$$\therefore t = \frac{8}{6}, \frac{40}{6}$$

$$\therefore t = 1\frac{1}{3} \text{ or } 6\frac{2}{3}$$

So, the population is 9000 at $1\frac{1}{3}$ weeks and $6\frac{2}{3}$ weeks.

ii When $P(t) = 6000$,

$$7500 + 3000 \sin\left(\frac{\pi t}{8}\right) = 6000$$

$$\therefore 3000 \sin\left(\frac{\pi t}{8}\right) = -1500$$

$$\therefore \sin\left(\frac{\pi t}{8}\right) = -\frac{1}{2}$$

The points on the unit circle with $\sin -\frac{1}{2}$ correspond to angles $\frac{7\pi}{6}$ and $\frac{11\pi}{6}$.

$$0 \leq t \leq 12 \quad \therefore 0 \leq \frac{\pi t}{8} \leq \frac{3\pi}{2}$$

$$\text{So } \frac{\pi t}{8} = \frac{7\pi}{6}$$

$$\therefore t = \frac{56}{6}$$

$$\therefore t = 9\frac{1}{3}$$

So, the population is 6000 at $9\frac{1}{3}$ weeks.

d If $P(t) > 10\,000$, then

$$7500 + 3000 \sin\left(\frac{\pi t}{8}\right) > 10\,000$$

$$\therefore 3000 \sin\left(\frac{\pi t}{8}\right) > 2500$$

$$\therefore \sin\left(\frac{\pi t}{8}\right) > \frac{5}{6}$$

Solving $\sin\left(\frac{\pi t}{8}\right) = \frac{5}{6}$ using technology

$$t \approx 2.51 \text{ or } 5.49 \quad \text{So, } 2.51 \leq t \leq 5.49 \text{ weeks.}$$

3 $H(t) = 20 - 19 \sin\left(\frac{2\pi t}{3}\right)$

a $H(0) = 20 - 19(0)$
 $= 20 \text{ m}$
 So, at time $t = 0$, the light is 20 m above the ground.

b H is lowest when $\sin\left(\frac{2\pi t}{3}\right) = 1$

$$\therefore \frac{2\pi t}{3} = \frac{\pi}{2} + k2\pi$$

$$\therefore \frac{2t}{3} = \frac{1}{2} + k2$$

$$\therefore t = \frac{3}{4} + k3$$

$$\therefore t = \frac{3}{4} \text{ min } \{\text{as } k = 0\}$$

c period $= \frac{2\pi}{\frac{2\pi}{3}} = 3 \text{ min}$
 $\therefore$ one revolution takes 3 minutes

d

4 $P(t) = 400 + 250 \sin\left(\frac{\pi t}{2}\right)$

a $P(0) = 400 + 250(0)$
 $= 400 \text{ water buffalo}$

c $P(1) = 400 + 250 \sin\left(\frac{\pi}{2}\right)$
 $= 400 + 250 \times 1$
 $= 650 \text{ water buffalo}$

This is the maximum herd size.

b **i** $P\left(\frac{1}{2}\right) = 400 + 250 \sin\left(\frac{\pi\left(\frac{1}{2}\right)}{2}\right)$
 $= 400 + 250 \sin\left(\frac{\pi}{4}\right)$
 $= 400 + 250 \times \frac{1}{\sqrt{2}}$
 $\approx 577 \text{ water buffalo}$

ii $P(2) = 400 + 250 \sin \pi$
 $= 400 + 250(0)$
 $= 400 \text{ water buffalo}$

- d** $P(t)$ is smallest when $\sin\left(\frac{\pi t}{2}\right) = -1$
and is $400 - 250 = 150$ water buffalo.

It occurs when

$$\frac{\pi t}{2} = \frac{3\pi}{2} + k2\pi$$

$$\therefore \frac{t}{2} = \frac{3}{2} + k2$$

$$\therefore t = 3 + 4k$$

So, the first time is after 3 years.

- 5 a** The period is 4 seconds.

$$\therefore \frac{2\pi}{b} = 4$$

$$\therefore b = \frac{\pi}{2}$$

Amplitude is 3 $\therefore a = 3$

- b** X enters the water when $H(t) = 2$

$$\therefore 3 \cos\left(\frac{\pi t}{2}\right) + 4 = 2$$

$$\therefore \cos\left(\frac{\pi t}{2}\right) = -\frac{2}{3}$$

Using technology, $t \approx 1.46$ seconds

- e** If $P(t) > 500$ then

$$400 + 250 \sin\left(\frac{\pi t}{2}\right) > 500$$

$$\therefore 250 \sin\left(\frac{\pi t}{2}\right) > 100$$

$$\therefore \sin\left(\frac{\pi t}{2}\right) > \frac{2}{5}$$

Using technology:

$$\sin\left(\frac{\pi t}{2}\right) = \frac{2}{5} \text{ when}$$

$$\frac{\pi t}{2} \approx 0.4115 \text{ or } \pi - 0.4115$$

$$\therefore t \approx 0.262 \text{ or } 1.74$$

$$\text{So, for } \sin\left(\frac{\pi t}{2}\right) > \frac{2}{5}, \quad 0.262 < t < 1.74$$

$\therefore$ the herd first exceeded 500 when
 $t \approx 0.262$ years.

$$d = 1 + 3 = 4, \quad c = 0$$

$$\therefore H(t) = 3 \cos\left(\frac{\pi}{2}(t - 0)\right) + 4 \text{ metres}$$

$$\therefore H(t) = 3 \cos\left(\frac{\pi}{2}t\right) + 4 \text{ metres}$$

Check: When $t = 0$, $H(0) = 3 \cos 0 + 4 = 7$ ✓

- 6** $C(t) = 9.2 \sin\left(\frac{\pi}{7}(t - 4)\right) + 107.8 \text{ cents L}^{-1}$

- a i** 107.8 is the median value. Values are between $107.8 - 9.2$ and $107.8 + 9.2$
 $= 98.6 \text{ cents L}^{-1}$ and $117.0 \text{ cents L}^{-1}$
 $\uparrow$ $\uparrow$
 min. max.
 $\therefore$ the statement is true.

- ii** period $= \frac{2\pi}{\frac{\pi}{7}} = 14$ days $\therefore$ true

- b** $C(7) = 9.2 \sin\left(\frac{\pi}{7}(3)\right) + 107.8 \approx 116.8 \text{ cents L}^{-1}$

- c** When $C(t) = \$1.10 \text{ L}^{-1}$ then $9.2 \sin\left(\frac{\pi}{7}(t - 4)\right) + 107.8 = 110$

$$\therefore \sin\left(\frac{\pi}{7}(t - 4)\right) = \frac{2.2}{9.2} \approx 0.23913$$

$$\begin{aligned} \therefore \frac{\pi}{7}(t - 4) &\approx 0.2415, \pi - 0.2415, \\ &2\pi + 0.2415, 3\pi - 0.2415 \\ &\approx 0.2415, 2.9001, 6.5247, 9.1833 \\ \therefore t - 4 &\approx 0.538, 6.462, 14.538, 20.462 \\ \therefore t &\approx 4.538, 10.462, 18.538, 24.462 \end{aligned}$$

So, the price is \$1.10 per litre on the 5th, 11th, 19th, and 25th days.

- d** The minimum cost per litre is $-9.2 + 107.8 = 98.6 \text{ cents L}^{-1}$

$$\text{when } \sin\left(\frac{\pi}{7}(t - 4)\right) = -1 \quad \therefore 2t - 8 = 21$$

$$\therefore \frac{\pi}{7}(t - 4) = \frac{3\pi}{2} \quad \therefore 2t = 29$$

$$\therefore \frac{t - 4}{7} = \frac{3}{2} \quad \therefore t = 14.5 \pm 14k$$

{period is 14 days}

So, the minimum occurred on the 1st day and the 15th day.

23 The period of a function $f(x)$ is the smallest $p > 0$ such that

$$f(x+p) = f(x) \text{ for all } x$$

$$\therefore \sin[n(x+p)] = \sin(nx)$$

$$\therefore \sin(nx+np) = \sin(nx)$$

$$\therefore \sin(nx) \cos(np) + \cos(nx) \sin(np) = \sin(nx)$$

Equating coefficients of $\sin(nx)$ and $\cos(nx)$,

$$\cos(np) = 1 \text{ and } \sin(np) = 0$$

$$\therefore np = 2k\pi, \quad k \in \mathbb{Z}$$

$$\therefore p = \frac{2k\pi}{n}, \quad k \in \mathbb{Z}$$

The smallest $p > 0$ occurs when $k = 1 \therefore p = \frac{2\pi}{n}$

 &= k[\cos x \cos b - \sin x \sin b] \\
 &= k \cos b \cos x - k \sin b \sin x
 \end{aligned}$$

Equating coefficients of $\cos x$ and $\sin x$,

$$k \cos b = 2 \text{ and } k \sin b = 5 \quad \dots (1)$$

$$\therefore k^2 \cos^2 b = 4 \text{ and } k^2 \sin^2 b = 25 \quad \{\text{squaring both sides}\}$$

$$\therefore k^2(\cos^2 b + \sin^2 b) = 29 \quad \{\text{adding the two equations}\}$$

$$\therefore k^2 = 29 \therefore k = \sqrt{29} \quad \{k > 0\}$$

Substituting $k = \sqrt{29}$ into (1) gives

$$\cos b = \frac{2}{\sqrt{29}} \text{ and } \sin b = \frac{5}{\sqrt{29}}$$

$$\therefore b = \cos^{-1}\left(\frac{2}{\sqrt{29}}\right) \approx 1.19$$

$$\therefore 2 \cos x - 5 \sin x \approx \sqrt{29} \cos(x + 1.19)$$

$$\mathbf{b} \quad 2 \cos x - 5 \sin x = -2$$

$$\therefore \sqrt{29} \cos(x + 1.19) \approx -2$$

$$\therefore \cos(x + 1.19) \approx -\frac{2}{\sqrt{29}}$$

$$\therefore x + 1.19 \approx 1.951, 4.33$$

 \therefore & \frac{2-2t^2-10t}{1+t^2} = -2 \\
 \therefore & 2-2t^2-10t = -2-2t^2 \\
 \therefore & 4 = 10t \\
 \therefore & t = \frac{2}{5}
 \end{aligned}$$

$$\text{So } \tan\left(\frac{x}{2}\right) = \frac{2}{5}$$

2 a $2 \sin x = -1$, $0 \leq x \leq 4\pi$
 $\therefore \sin x = -\frac{1}{2}$

The points on the unit circle with sine $-\frac{1}{2}$
 correspond to angles $\frac{7\pi}{6}$ and $\frac{11\pi}{6}$.

$\therefore x = \frac{7\pi}{6}, \frac{11\pi}{6}, \frac{19\pi}{6}, \frac{23\pi}{6}$

The points on the unit circle with sine $\frac{1}{\sqrt{2}}$
 correspond to angles $\frac{\pi}{4}$ and $\frac{3\pi}{4}$.

3 a $2 \sin 3x + \sqrt{3} = 0$, $0 \leq x \leq 2\pi$
 $\therefore \sin 3x = -\frac{\sqrt{3}}{2}$

The points on the unit circle with sine $-\frac{\sqrt{3}}{2}$
 correspond to angles $\frac{4\pi}{3}$ and $\frac{5\pi}{3}$.

$0 \leq x \leq 2\pi \therefore 0 \leq 3x \leq 6\pi$

So $3x = \frac{4\pi}{3}, \frac{5\pi}{3}, \frac{10\pi}{3}, \frac{11\pi}{3}, \frac{16\pi}{3}, \frac{17\pi}{3}$

So, the x -intercepts are

$\frac{4\pi}{9}, \frac{5\pi}{9}, \frac{10\pi}{9}, \frac{11\pi}{9}, \frac{16\pi}{9}, \frac{17\pi}{9}$.

b $\sqrt{2} \sin(x + \frac{\pi}{4}) = 0$, $0 \leq x \leq 3\pi$
 $\therefore \sin(x + \frac{\pi}{4}) = 0$

The points on the unit circle with sine 0
 correspond to angles 0 and π .

$0 \leq x \leq 3\pi \therefore \frac{\pi}{4} \leq x + \frac{\pi}{4} \leq \frac{13\pi}{4}$

So $x + \frac{\pi}{4} = \pi, 2\pi, 3\pi$

So, the x -intercepts are $\frac{3\pi}{4}, \frac{7\pi}{4}, \frac{11\pi}{4}$.

EXERCISE 14A.1

EXERCISE 14A.2

- 1**
 - a** If they are equal in magnitude, they have the same length. These are **p**, **q**, **s**, and **t**.
 - b** Those parallel are **p**, **q**, **r**, and **t**.
 - c** Those in the same direction are: **p** and **r**, **q** and **t**.
 - d** To be equal they must have the same direction and be equal in length $\therefore \mathbf{q} = \mathbf{t}$.
 - e** **p** and **q** are negatives (equal length, but opposite direction). Likewise, **p** and **t** are negatives. We write $\mathbf{p} = -\mathbf{q}$ and $\mathbf{p} = -\mathbf{t}$.
- 2**
 - a** True, as they have the same length and direction.
 - b** True, as they are sides of an equilateral triangle.
 - c** False, as they do not have the same direction.
 - d** False, as they have opposite directions.
 - e** True, as they have the same length and direction.
 - f** False, as they do not have the same direction.

- 3 a i** $\overrightarrow{BC}$ is the vector which originates at B and terminates at C.
ii $\overrightarrow{ED} = \overrightarrow{AB}$, as they have the same length and direction.
- b i** $\overrightarrow{FE}$ and $\overrightarrow{BC}$ are negatives of $\overrightarrow{EF}$, as they both have the same length but opposite direction.
ii All sides of the hexagon are equal in length
 $\therefore$ the vectors with the same length as $\overrightarrow{ED}$ are
 $\overrightarrow{DE}$, $\overrightarrow{EF}$, $\overrightarrow{FE}$, $\overrightarrow{FA}$, $\overrightarrow{AF}$, $\overrightarrow{AB}$, $\overrightarrow{BA}$, $\overrightarrow{BC}$, $\overrightarrow{CB}$, $\overrightarrow{CD}$, and $\overrightarrow{DC}$.
- c** The vector $\overrightarrow{FC}$ is parallel to $\overrightarrow{AB}$ and twice its length.
 $\overrightarrow{CF}$ is also parallel to $\overrightarrow{AB}$ and twice its length (but in the opposite direction).

EXERCISE 14B.1

- 2 a** $\overrightarrow{AB} + \overrightarrow{BC} = \overrightarrow{AC}$
- b** $\overrightarrow{BC} + \overrightarrow{CD} = \overrightarrow{BD}$
- c** $\overrightarrow{AB} + \overrightarrow{BA} = \overrightarrow{AA} = \mathbf{0}$
- d** $\overrightarrow{AB} + \overrightarrow{BC} + \overrightarrow{CD} = \overrightarrow{AC} + \overrightarrow{CD} = \overrightarrow{AD}$
- e** $\overrightarrow{AC} + \overrightarrow{CB} + \overrightarrow{BD} = \overrightarrow{AB} + \overrightarrow{BD} = \overrightarrow{AD}$
- f** $\overrightarrow{BC} + \overrightarrow{CA} + \overrightarrow{AB} = \overrightarrow{BA} + \overrightarrow{AB} = \overrightarrow{BB} = \mathbf{0}$

- 4** $\overrightarrow{PS} = \overrightarrow{PR} + \overrightarrow{RS} = (\mathbf{a} + \mathbf{b}) + \mathbf{c}$
- But $\overrightarrow{PS} = \overrightarrow{PQ} + \overrightarrow{QS} = \mathbf{a} + (\mathbf{b} + \mathbf{c})$
- $\therefore (\mathbf{a} + \mathbf{b}) + \mathbf{c} = \mathbf{a} + (\mathbf{b} + \mathbf{c})$ {as both are equal to $\overrightarrow{PS}$, associative law}

- 5 a** Scale: 1 cm = 100 km h⁻¹

- b** We need to perform vector addition to find the effect of the wind on the aeroplane.

- c** Measuring the length of the resulting vector, we get 82.5 mm, or 8.25 cm.

$\therefore$ the resulting speed of the plane is $8.25 \times 100 = 825 \text{ km h}^{-1}$.

Using a protractor to measure the angle between 'true north' and the resulting vector, we get 88° .

$\therefore$ the direction of the aeroplane is 88° east of north.

d The position vector of B relative to C

$$= \vec{CB} = \begin{pmatrix} 2 - (-3) \\ 0 - 1 \\ 3 - 0 \end{pmatrix} = \begin{pmatrix} 5 \\ -1 \\ 3 \end{pmatrix}$$

$$\begin{aligned} \therefore CB &= \sqrt{5^2 + (-1)^2 + 3^2} \\ &= \sqrt{25 + 1 + 9} \\ &= \sqrt{35} \text{ units} \end{aligned}$$

e Triangle ABC has $AC = \sqrt{30}$ units, $CB = \sqrt{35}$ units, and $AB = \sqrt{17}$ units.All the side lengths are different, and $(\sqrt{17})^2 + (\sqrt{30})^2 \neq (\sqrt{35})^2$. $\therefore$ triangle ABC is scalene, and not right angled.

- a** The distance from Q to the Y-axis is the distance from Q to $Y'(0, 1, 0)$.

$$\begin{aligned}\therefore QY' &= \sqrt{(3-0)^2 + (1-1)^2 + (-2-0)^2} \\ &= \sqrt{9+4} \\ &= \sqrt{13} \text{ units}\end{aligned}$$

- b** The distance from Q to the origin is

$$\begin{aligned}QO &= \sqrt{(3-0)^2 + (1-0)^2 + (-2-0)^2} \\ &= \sqrt{9+1+4} \\ &= \sqrt{14} \text{ units}\end{aligned}$$

- c** The distance from Q to the ZOY plane is the distance from Q to $(0, 1, -2)$, which is 3 units.

- 8** $P(0, 4, 4)$, $Q(2, 6, 5)$, $R(1, 4, 3)$

$$\begin{aligned}PQ &= \sqrt{(2-0)^2 + (6-4)^2 + (5-4)^2} \\ &= \sqrt{4+4+1} \\ &= 3\end{aligned}$$

$$\begin{aligned}PR &= \sqrt{(1-0)^2 + (4-4)^2 + (3-4)^2} \\ &= \sqrt{1+0+1} \\ &= \sqrt{2}\end{aligned}$$

$$\begin{aligned}QR &= \sqrt{(1-2)^2 + (4-6)^2 + (3-5)^2} \\ &= \sqrt{1+4+4} \\ &= 3\end{aligned}$$

$\therefore PQ = QR$ and so $\triangle PQR$ is isosceles.

- 9 a** $A(0, 0, 3)$, $B(2, 8, 1)$, $C(-9, 6, 18)$

$$\begin{aligned}AB &= \sqrt{(2-0)^2 + (8-0)^2 + (1-3)^2} \\ &= \sqrt{4+64+4} \\ &= \sqrt{72}\end{aligned}$$

$$\begin{aligned}AC &= \sqrt{(-9-0)^2 + (6-0)^2 + (18-3)^2} \\ &= \sqrt{81+36+225} \\ &= \sqrt{342}\end{aligned}$$

$$\begin{aligned}BC &= \sqrt{(-9-2)^2 + (6-8)^2 + (18-1)^2} \\ &= \sqrt{121+4+289} \\ &= \sqrt{414}\end{aligned}$$

Since $BC^2 = AB^2 + AC^2$,
 $\triangle ABC$ is right angled.

- b** $A(1, 0, -3)$, $B(2, 2, 0)$, $C(4, 6, 6)$

$$\begin{aligned}AB &= \sqrt{(2-1)^2 + (2-0)^2 + (0-(-3))^2} \\ &= \sqrt{1+4+9} \\ &= \sqrt{14}\end{aligned}$$

$$\begin{aligned}AC &= \sqrt{(4-1)^2 + (6-0)^2 + (6-(-3))^2} \\ &= \sqrt{9+36+81} \\ &= \sqrt{126} = 3\sqrt{14}\end{aligned}$$

$$\begin{aligned}BC &= \sqrt{(4-2)^2 + (6-2)^2 + (6-0)^2} \\ &= \sqrt{4+16+36} \\ &= \sqrt{56} = 2\sqrt{14}\end{aligned}$$

Since $AB + BC = AC$, the points A, B, and C lie on a straight line, so they do not form a triangle.

10 a $\vec{AB} = \begin{pmatrix} 6-5 \\ 12-6 \\ 9-(-2) \end{pmatrix} = \begin{pmatrix} 1 \\ 6 \\ 11 \end{pmatrix}$

$$\begin{aligned}\text{and so } |\vec{AB}| &= \sqrt{1^2 + 6^2 + 11^2} \\ &= \sqrt{1+36+121} \\ &= \sqrt{158} \text{ units}\end{aligned}$$

$$\vec{AC} = \begin{pmatrix} 2-5 \\ 4-6 \\ 2-(-2) \end{pmatrix} = \begin{pmatrix} -3 \\ -2 \\ 4 \end{pmatrix}$$

$$\begin{aligned}\text{and so } |\vec{AC}| &= \sqrt{(-3)^2 + (-2)^2 + 4^2} \\ &= \sqrt{9+4+16} \\ &= \sqrt{29} \text{ units}\end{aligned}$$

$$\vec{BC} = \begin{pmatrix} 2-6 \\ 4-12 \\ 2-9 \end{pmatrix} = \begin{pmatrix} -4 \\ -8 \\ -7 \end{pmatrix}$$

$$\begin{aligned}\text{and so } |\vec{BC}| &= \sqrt{(-4)^2 + (-8)^2 + (-7)^2} \\ &= \sqrt{16+64+49} \\ &= \sqrt{129} \text{ units}\end{aligned}$$

$$\begin{aligned}\text{Now, } (\sqrt{29})^2 + (\sqrt{129})^2 &= 29 + 129 \\ &= 158 \\ &= (\sqrt{158})^2\end{aligned}$$

$$\text{So, } AC^2 + BC^2 = AB^2$$

$\therefore$ triangle ABC is right angled with the right angle at C.

$$\begin{aligned}\text{Area} &= \frac{1}{2} \times \text{base} \times \text{height} \\ &= \frac{1}{2} \times \sqrt{129} \times \sqrt{29} \\ &\approx 30.6 \text{ units}^2\end{aligned}$$

11

If B is (a, b, c) then $\frac{a-2}{2} = -1$, $\frac{b+1}{2} = 2$, $\frac{c+3}{2} = 4$

$$\therefore a = 0, \quad b = 3, \quad c = 5$$

$$\therefore \text{B is } (0, 3, 5)$$

$$\begin{aligned}r = AC &= \sqrt{(-1 - (-2))^2 + (2 - 1)^2 + (4 - 3)^2} \\ &= \sqrt{1 + 1 + 1} \\ &= \sqrt{3} \text{ units}\end{aligned}$$

12 a $(0, y, 0)$ for any y **b** The distance between $(0, y, 0)$ and $B(-1, -1, 2)$ is $\sqrt{(-1)^2 + (-1 - y)^2 + 2^2}$.

$$\therefore \sqrt{1 + (y + 1)^2 + 4} = \sqrt{14}$$

$$\therefore (y + 1)^2 = 9$$

$$\therefore y + 1 = \pm 3$$

$$\therefore y = -1 \pm 3$$

$$\therefore y = -4 \text{ or } 2 \quad \therefore \text{the two points are } (0, -4, 0) \text{ and } (0, 2, 0).$$

13

a $\begin{pmatrix} a-4 \\ b-3 \\ c+2 \end{pmatrix} = \begin{pmatrix} 1 \\ 3 \\ -4 \end{pmatrix}$

$$\therefore \begin{cases} a-4=1 \\ b-3=3 \\ c+2=-4 \end{cases}$$

$$\therefore a = 5, \quad b = 6, \quad c = -6$$

b $\begin{pmatrix} a-5 \\ b-2 \\ c+3 \end{pmatrix} = \begin{pmatrix} 3-a \\ 2-b \\ 5-c \end{pmatrix}$

$$\therefore \begin{cases} a-5=3-a \\ b-2=2-b \\ c+3=5-c \end{cases}$$

$$\therefore 2a = 8, \quad 2b = 4, \quad 2c = 2$$

$$\therefore a = 4, \quad b = 2, \quad c = 1$$

14**a** length = 1

b

$$\therefore \sqrt{k^2 + \frac{4}{9} + \frac{1}{9}} = 1$$

$$\therefore \sqrt{k^2 + \frac{5}{9}} = 1$$

$$\therefore k^2 = \frac{4}{9}$$

$$\therefore k = \pm \frac{2}{3}$$

$$\therefore r - 2 = 0, \quad s - 5 = -1, \quad \text{and} \quad t + 1 = -6 \quad \therefore r = 2, \quad s = 4, \quad \text{and} \quad t = -7$$

b ABCD is a parallelogram since its opposite sides are parallel and equal in length.

17 **a** Suppose S is at (x, y, z) . $\overrightarrow{PQ} = \overrightarrow{SR}$ {opposite sides are parallel and equal in length}

$$\therefore \begin{pmatrix} 1-(-1) \\ -2-2 \\ 5-3 \end{pmatrix} = \begin{pmatrix} 0-x \\ 4-y \\ -1-z \end{pmatrix}$$

$$\therefore \begin{pmatrix} 2 \\ -4 \\ 2 \end{pmatrix} = \begin{pmatrix} -x \\ 4-y \\ -1-z \end{pmatrix}$$

$$\begin{aligned} \therefore -x &= 2 & 4-y &= -4 & -1-z &= 2 \\ \therefore x &= -2 & y &= 8 & z &= -3 \\ \therefore S &\text{ is at } (-2, 8, -3). \end{aligned}$$

b The midpoint of [PR] is $\left(\frac{-1+0}{2}, \frac{2+4}{2}, \frac{3+(-1)}{2} \right)$ which is $(-\frac{1}{2}, 3, 1)$.

The midpoint of [QS] is $\left(\frac{1+(-2)}{2}, \frac{-2+8}{2}, \frac{5+(-3)}{2} \right)$ which is $(-\frac{1}{2}, 3, 1)$.

So, [PR] and [QS] have the same midpoint. ✓

12 Case: **a** and **b** are not parallel.

Since **a**, **b**, and **c** form a triangle,

length of **a** + length of **b** > length of **c**

But **c** = **a** + **b**, so length of **c** = length of (**a** + **b**)

$\therefore$ length of **a** + length of **b** > length of (**a** + **b**)

$$\therefore |\mathbf{a}| + |\mathbf{b}| > |\mathbf{a} + \mathbf{b}|$$

Case: **a** and **b** are parallel.

length of **a** + length of **b** = length of (**a** + **b**)

$$\therefore |\mathbf{a}| + |\mathbf{b}| = |\mathbf{a} + \mathbf{b}|$$

These are the only possible cases, so $\therefore$ for any **a**, **b**, $|\mathbf{a}| + |\mathbf{b}| \geq |\mathbf{a} + \mathbf{b}|$

(2) – (1) gives $t = -4$ and so $s = 5$

$$\therefore \mathbf{a} \bullet \mathbf{b} = 0$$

$\therefore \mathbf{a}$ and $\mathbf{b}$ are perpendicular.

b

As shown $\mathbf{a} + \mathbf{b}$ and $\mathbf{a} - \mathbf{b}$ are the diagonals of a parallelogram with side lengths $|\mathbf{a}|$ and $|\mathbf{b}|$.

Now if $|\mathbf{a} + \mathbf{b}| = |\mathbf{a} - \mathbf{b}|$ then the parallelogram must be a square, and $\mathbf{a}$ is perpendicular to $\mathbf{b}$.

$$\begin{aligned}
 \mathbf{26} \quad & (\mathbf{a} + \mathbf{b}) \bullet (\mathbf{a} - \mathbf{b}) \\
 &= \mathbf{a} \bullet \mathbf{a} - \mathbf{a} \bullet \mathbf{b} + \mathbf{b} \bullet \mathbf{a} - \mathbf{b} \bullet \mathbf{b} \\
 &= |\mathbf{a}|^2 - |\mathbf{b}|^2 \\
 &= 3^2 - 4^2 \\
 &= 9 - 16 \\
 &= -7
 \end{aligned}$$

27 The dot product is only defined for two vectors. For $\mathbf{a} \bullet \mathbf{b} \bullet \mathbf{c}$, the result of $\mathbf{a} \bullet \mathbf{b}$ is a scalar, and the dot product of the scalar and $\mathbf{c}$ is meaningless.

So, $\overrightarrow{WY} = \overrightarrow{XZ}$
 $\therefore$ [WY] is parallel to [XZ] and they are equal in length. This is sufficient to deduce that WYZX is a parallelogram.

Now $\overrightarrow{AB} \bullet \overrightarrow{AC} = 0$ {as $\widehat{BAC} = 90^\circ$ }
 $\therefore \begin{pmatrix} -3 \\ 1 \end{pmatrix} \bullet \begin{pmatrix} 1 \\ k - 3 \end{pmatrix} = 0$
 $\therefore -3 + k - 3 = 0$
 $\therefore k = 6$

11 a $\mathbf{a} \bullet \mathbf{b}$ is a scalar, so $\mathbf{a} \bullet \mathbf{b} \bullet \mathbf{c}$ is a scalar dotted with a vector, which is meaningless.

b $\mathbf{b} \times \mathbf{c}$ must be done first otherwise we have the cross product of a scalar with a vector, which is meaningless.

12 One vector perpendicular to $\begin{pmatrix} -4 \\ 5 \end{pmatrix}$ is $\begin{pmatrix} 5 \\ 4 \end{pmatrix}$ as the dot product $= -20 + 20 = 0$

$\therefore$ all vectors have the form $t \begin{pmatrix} 5 \\ 4 \end{pmatrix}$, $t \neq 0$.

$$\therefore k = \pm \frac{1}{2}$$

b $\begin{pmatrix} 3 \\ 2 \\ -1 \end{pmatrix}$ has length $\sqrt{3^2 + 2^2 + (-1)^2} = \sqrt{14}$ units

$\therefore$ a unit vector in the opposite direction is $-\frac{1}{\sqrt{14}} \begin{pmatrix} 3 \\ 2 \\ -1 \end{pmatrix}$

$\therefore$ a vector of length 5 units in the opposite direction is $-\frac{5}{\sqrt{14}} \begin{pmatrix} 3 \\ 2 \\ -1 \end{pmatrix}$.

18 Using $\theta = \cos^{-1} \left(\frac{\mathbf{u} \bullet \mathbf{v}}{|\mathbf{u}| |\mathbf{v}|} \right)$,

$$\mathbf{u} \bullet \mathbf{v} = \begin{pmatrix} 2 \\ -4 \\ 3 \end{pmatrix} \bullet \begin{pmatrix} -1 \\ 1 \\ 3 \end{pmatrix}$$

$$= -2 - 4 + 9$$

$$= 3$$

$$|\mathbf{u}| = \sqrt{2^2 + (-4)^2 + 3^2}$$

$$= \sqrt{4 + 16 + 9}$$

$$= \sqrt{29}$$

$$|\mathbf{v}| = \sqrt{(-1)^2 + 1^2 + 3^2}$$

$$= \sqrt{1 + 1 + 9}$$

$$= \sqrt{11}$$

$$\therefore \theta = \cos^{-1} \left(\frac{3}{\sqrt{29}\sqrt{11}} \right)$$

or using $\theta = \sin^{-1} \left(\frac{|\mathbf{u} \times \mathbf{v}|}{|\mathbf{u}| |\mathbf{v}|} \right)$,

$$= -15\mathbf{i} - 9\mathbf{j} - 2\mathbf{k}$$

$$|\mathbf{u} \times \mathbf{v}| = \sqrt{(-15)^2 + (-9)^2 + (-2)^2}$$

$$= \sqrt{310}$$

Chapter 15

VECTOR APPLICATIONS

EXERCISE 15A

1 a

If the athlete is assisted by a wind of 1 m s^{-1} his speed will be 7 m s^{-1} .

b

If the athlete runs into a head wind of 1 m s^{-1} his speed will be 5 m s^{-1} .

2 a

$$\begin{aligned} (\text{actual speed})^2 &= (\text{swimming speed})^2 + (\text{current})^2 \\ &= 1.2^2 + 0.6^2 \\ &= 1.8 \end{aligned}$$

$$\therefore \text{actual speed} = \sqrt{1.8} \approx 1.34 \text{ m s}^{-1}$$

$$\tan \theta = \frac{0.6}{1.2}$$

$$\therefore \theta \approx 26.6^\circ$$

$\therefore$ Mary's actual velocity is approximately 1.34 m s^{-1} in the direction 26.6° to the left of her intended line.

b i

Mary needs to aim to the right of Q so the current will correct her direction.

$$\sin \phi = \frac{0.6}{1.2}$$

$$\therefore \phi = 30^\circ$$

$\therefore$ Mary should aim to swim 30° to the right of Q.

ii

$$\begin{aligned} (\text{swimming speed})^2 &= (\text{actual speed})^2 + (\text{current})^2 \\ \therefore (\text{actual speed})^2 &= 1.2^2 - 0.6^2 \\ &= 1.08 \end{aligned}$$

$$\therefore \text{Mary's actual speed} = \sqrt{1.08} \approx 1.04 \text{ m s}^{-1}$$

3

a Using the cosine rule,

$$V^2 = 20^2 + 6^2 - 2 \times 20 \times 6 \times \cos 135^\circ$$

$$\therefore V \approx 24.6$$

$\therefore$ the equivalent speed in still water is 24.6 km h^{-1} .

b Using the sine rule,

$$\frac{\sin \theta}{6} \approx \frac{\sin 135^\circ}{24.61}$$

$$\therefore \theta \approx \sin^{-1} \left(\frac{6 \times \sin 135^\circ}{24.61} \right)$$

$$\therefore \theta \approx 9.93^\circ$$

$\therefore$ the boat should head 9.93° east of south.

4

a $d^2 = 80^2 + 20^2$ {Pythagoras}

$$\therefore d = \sqrt{80^2 + 20^2} \quad \{d > 0\}$$

$$\therefore d \approx 82.5$$

$\therefore$ the distance from X to Y is about 82.5 m.

$$\begin{aligned} \mathbf{b} \quad \alpha &= \tan^{-1}\left(\frac{20}{80}\right) \approx 14.04^\circ \\ \therefore \theta &\approx 90^\circ + 14.04^\circ \quad \{\text{exterior angle of } \triangle\} \\ \therefore \theta &\approx 104.04^\circ \end{aligned}$$

In t seconds, Stephanie can swim $1.8t$ metres, and the current will move $0.3t$ metres.

$$\therefore |\mathbf{s}| = 1.8t \quad \text{and} \quad |\mathbf{c}| = 0.3t$$

Using the sine rule,

$$\frac{\sin \beta}{0.3t} = \frac{\sin \theta}{1.8t}$$

$$\beta \approx \sin^{-1}\left(\frac{0.3 \times \sin 104.04^\circ}{1.8}\right)$$

$$\therefore \beta \approx 9.31^\circ$$

$$\therefore \alpha + \beta \approx 23.3^\circ$$

$\therefore$ Stephanie should head 23.3° to the left of the perpendicular across the river.

$$\mathbf{c} \quad \tan(\alpha + \beta) = \frac{20 + 0.3t}{80}$$

$$\therefore 20 + 0.3t \approx 80 \tan(23.34^\circ)$$

$$\therefore t \approx \frac{80 \tan(23.34^\circ) - 20}{0.3}$$

$$\therefore t \approx 48.4$$

$\therefore$ Stephanie will take 48.4 seconds to cross the river.

5

$\mathbf{a}$ Using the cosine rule,

$$x^2 = 50^2 + 400^2 - 2 \times 50 \times 400 \cos 135^\circ$$

$$\therefore x \approx 436.79$$

The aeroplane should fly so that its speed in still air would be 437 km h^{-1} .

The wind slows the aeroplane down to 400 km h^{-1} .

$\mathbf{b}$ Using the sine rule,

$$\frac{\sin \theta}{50} \approx \frac{\sin 135^\circ}{436.79}$$

$$\therefore \theta \approx 4.64^\circ$$

The aeroplane should head 4.64° north of east.

2 Given $A(-1, 2, 2)$, $B(2, -1, 4)$, and $C(0, 1, 0)$, $\vec{AB} = \begin{pmatrix} 3 \\ -3 \\ 2 \end{pmatrix}$ and $\vec{AC} = \begin{pmatrix} 1 \\ -1 \\ -2 \end{pmatrix}$.

$$\therefore \text{area of parallelogram} = |8\mathbf{i} + 8\mathbf{j}| = \sqrt{8^2 + 8^2} = 8\sqrt{2} \text{ units}^2$$

3 a

Suppose D is at (a, b, c) .

Since $\vec{AB} = \vec{DC}$,

$$\begin{pmatrix} 3 \\ -3 \\ 2 \end{pmatrix} = \begin{pmatrix} -1 - a \\ -2 - b \\ 5 - c \end{pmatrix}$$

$$\therefore -1 - a = 3, \quad -2 - b = -3, \quad \text{and} \quad 5 - c = 2$$

$$\therefore a = -4, \quad b = 1, \quad \text{and} \quad c = 3$$

$\therefore$ D is at $(-4, 1, 3)$.

b $\vec{BC} = \begin{pmatrix} -3 \\ -2 \\ 1 \end{pmatrix}$ and $\vec{BA} = \begin{pmatrix} -3 \\ 3 \\ -2 \end{pmatrix}$

$$\begin{aligned} \therefore \vec{BC} \times \vec{BA} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -3 & -2 & 1 \\ -3 & 3 & -2 \end{vmatrix} = \begin{vmatrix} -2 & 1 \\ 3 & -2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} -3 & 1 \\ -3 & -2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} -3 & -2 \\ -3 & 3 \end{vmatrix} \mathbf{k} \\ &= \mathbf{i} - 9\mathbf{j} - 15\mathbf{k} \end{aligned}$$

$$\therefore \text{area} = |\mathbf{i} - 9\mathbf{j} - 15\mathbf{k}| = \sqrt{1^2 + (-9)^2 + (-15)^2} = \sqrt{307} \text{ units}^2$$

4 Now $\vec{AB} = \begin{pmatrix} 3 \\ -1 \\ -1 \end{pmatrix}$ and $\vec{AC} = \begin{pmatrix} k+1 \\ 1 \\ -3 \end{pmatrix}$

$$\text{Area of } \triangle ABC = \frac{1}{2} |\vec{AC} \times \vec{AB}|$$

$$\therefore \sqrt{88} = \frac{1}{2} \left| \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ k+1 & 1 & -3 \\ 3 & -1 & -1 \end{vmatrix} \right| = \frac{1}{2} \left| \begin{vmatrix} 1 & -3 \\ -1 & -1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} k+1 & -3 \\ 3 & -1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} k+1 & 1 \\ 3 & -1 \end{vmatrix} \mathbf{k} \right|$$

$$\therefore \sqrt{352} = |(-1-3)\mathbf{i} - (-(k+1)-9)\mathbf{j} + (-(k+1)-3)\mathbf{k}|$$

$$\therefore \sqrt{352} = |-4\mathbf{i} + (k-8)\mathbf{j} + (-k-4)\mathbf{k}|$$

$$\therefore \sqrt{352} = \sqrt{16 + (k-8)^2 + (-k-4)^2}$$

$$\therefore 352 = 16 + k^2 - 16k + 64 + k^2 + 8k + 16$$

$$\therefore 2k^2 - 8k - 256 = 0$$

$$\therefore k^2 - 4k - 128 = 0$$

$$\therefore k = \frac{4 \pm \sqrt{16 + 4(1)(128)}}{2} = 2 \pm \sqrt{132} = 2 \pm 2\sqrt{33}$$

8 Given $x = 1 - \lambda$, $y = 3 + \lambda$, $z = 3 - 2\lambda$:

$\mathbf{a}$ The line meets the XOY plane when $z = 0$ $\therefore 3 - 2\lambda = 0$
 $\therefore \lambda = \frac{3}{2}$

Then $x = 1 - \frac{3}{2} = -\frac{1}{2}$ and $y = 3 + \frac{3}{2} = \frac{9}{2}$, so the point is $(-\frac{1}{2}, \frac{9}{2}, 0)$.

$\mathbf{b}$ The line meets the YOZ plane when $x = 0$ $\therefore 1 - \lambda = 0$
 $\therefore \lambda = 1$

Then $y = 3 + 1 = 4$ and $z = 3 - 2 = 1$, so the point is $(0, 4, 1)$.

$\mathbf{c}$ The line meets the XOZ plane when $y = 0$ $\therefore 3 + \lambda = 0$
 $\therefore \lambda = -3$

Then $x = 1 - (-3) = 4$ and $z = 3 - 2(-3) = 9$, so the point is $(4, 0, 9)$.

10 Given a line with equations $x = 2 - \lambda$, $y = 3 + 2\lambda$, and $z = 1 + \lambda$,

the distance to the point $(1, 0, -2)$ is $\sqrt{(2-\lambda-1)^2 + (3+2\lambda-0)^2 + (1+\lambda+2)^2}$.

But this distance $= 5\sqrt{3}$ units

$$\therefore \sqrt{(1-\lambda)^2 + (3+2\lambda)^2 + (\lambda+3)^2} = 5\sqrt{3}$$

$$\therefore (1-\lambda)^2 + (3+2\lambda)^2 + (\lambda+3)^2 = 75$$

$$\therefore 1 - 2\lambda + \lambda^2 + 9 + 12\lambda + 4\lambda^2 + \lambda^2 + 6\lambda + 9 = 75$$

$$\therefore 6\lambda^2 + 16\lambda - 56 = 0$$

$$\therefore 3\lambda^2 + 8\lambda - 28 = 0$$

$$\therefore (3\lambda + 14)(\lambda - 2) = 0$$

$$\therefore \lambda = -\frac{14}{3} \quad \text{or} \quad \lambda = 2$$

When $\lambda = 2$, the point is $(0, 7, 3)$, and when $\lambda = -\frac{14}{3}$, the point is $(\frac{20}{3}, -\frac{19}{3}, -\frac{11}{3})$.

- 11 a** Let $A(1 + \lambda, 2 - \lambda, 3 + \lambda)$ be a point on the line such that $\overrightarrow{PA}$ is perpendicular to the line.

$$\text{Then } \overrightarrow{PA} = \begin{pmatrix} 1 + \lambda - 1 \\ 2 - \lambda - 1 \\ 3 + \lambda - 2 \end{pmatrix} = \begin{pmatrix} \lambda \\ 1 - \lambda \\ 1 + \lambda \end{pmatrix}$$

$$\begin{aligned} \text{and } PA &= \sqrt{\lambda^2 + (1 - \lambda)^2 + (1 + \lambda)^2} \\ &= \sqrt{\lambda^2 + (1 - 2\lambda + \lambda^2) + (1 + 2\lambda + \lambda^2)} \\ &= \sqrt{3\lambda^2 + 2} \text{ units} \end{aligned}$$

$[PA]$ is perpendicular to the line when $PA^2 = 3\lambda^2 + 2$ is minimised,

$$\text{which occurs when } \lambda = -\frac{b}{2a} = -\frac{0}{6} = 0$$

$\therefore$ A is at $(1 + 0, 2 - 0, 3 + 0)$

- b** Let A be a point on the line such that $\overrightarrow{PA}$ is perpendicular to the line.

$\therefore$ A is at $(1 + \mu, 2 - \mu, 2\mu)$ for some μ .

$$\text{Now } \overrightarrow{PA} = \begin{pmatrix} 1 + \mu - 2 \\ 2 - \mu - 1 \\ 2\mu - 3 \end{pmatrix} = \begin{pmatrix} \mu - 1 \\ 1 - \mu \\ 2\mu - 3 \end{pmatrix}$$

$$\begin{aligned} \text{and } PA &= \sqrt{(\mu - 1)^2 + (1 - \mu)^2 + (2\mu - 3)^2} \\ &= \sqrt{\mu^2 - 2\mu + 1 + 1 - 2\mu + \mu^2 + 4\mu^2 - 12\mu + 9} \\ &= \sqrt{6\mu^2 - 16\mu + 11} \text{ units} \end{aligned}$$

$[PA]$ is perpendicular to the line when $PA^2 = 6\mu^2 - 16\mu + 11$ is minimised,

$$\text{which occurs when } \mu = -\frac{b}{2a} = -\frac{-16}{12} = \frac{4}{3}$$

$\therefore$ A is at $(1 + \frac{4}{3}, 2 - \frac{4}{3}, 2(\frac{4}{3}))$

$\therefore$ the foot of the perpendicular is $(\frac{7}{3}, \frac{2}{3}, \frac{8}{3})$.

EXERCISE 15D

- 1** L_1 has direction vector $\begin{pmatrix} 12 \\ 5 \end{pmatrix}$ and L_2 has direction vector $\begin{pmatrix} 3 \\ -4 \end{pmatrix}$.

$$\begin{aligned} \text{If } \theta \text{ is the angle between them, } \cos \theta &= \frac{\left| \begin{pmatrix} 12 \\ 5 \end{pmatrix} \cdot \begin{pmatrix} 3 \\ -4 \end{pmatrix} \right|}{\sqrt{144 + 25} \sqrt{9 + 16}} \\ &= \frac{|36 + (-20)|}{13 \times 5} \\ &= \frac{16}{65} \end{aligned}$$

$$\therefore \theta = \cos^{-1} \left(\frac{16}{65} \right)$$

$$\therefore \theta \approx 75.7^\circ$$

- 2** Line 1 has direction vector $\begin{pmatrix} 5 \\ -2 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 4 \\ 10 \end{pmatrix}$

$$\text{and } \begin{pmatrix} 5 \\ -2 \end{pmatrix} \cdot \begin{pmatrix} 4 \\ 10 \end{pmatrix} = 20 + (-20) = 0$$

$\therefore$ the lines are perpendicular.

- 3** L_1 has direction vector $\begin{pmatrix} 4 \\ -3 \end{pmatrix}$ and L_2 has direction vector $\begin{pmatrix} 5 \\ 4 \end{pmatrix}$.

$$\begin{aligned} \text{If } \theta \text{ is the angle between them, } \cos \theta &= \frac{\left| \begin{pmatrix} 4 \\ -3 \end{pmatrix} \cdot \begin{pmatrix} 5 \\ 4 \end{pmatrix} \right|}{\sqrt{16+9}\sqrt{25+16}} \\ &= \frac{|20 + (-12)|}{\sqrt{25 \times 41}} \\ &= \frac{8}{\sqrt{25 \times 41}} \end{aligned}$$

$$\therefore \theta = \cos^{-1} \left(\frac{8}{\sqrt{25 \times 41}} \right)$$

$$\therefore \theta \approx 75.5^\circ$$

$\therefore$ the required angle measures 75.5° .

4 a $L_1: s = \frac{x-8}{3} = \frac{9-y}{16} = \frac{z-10}{7}$

$$\begin{aligned} 3s &= x-8 & \text{and} & & 16s &= 9-y & \text{and} & & 7s &= z-10 \\ \therefore x &= 8+3s & & & y &= 9-16s & & & z &= 10+7s \end{aligned}$$

$$\therefore \text{ line 1 has direction vector } \begin{pmatrix} 3 \\ -16 \\ 7 \end{pmatrix} \text{ and line 2 has direction vector } \begin{pmatrix} 3 \\ 8 \\ -5 \end{pmatrix}.$$

If θ is the angle between them,

$$\cos \theta = \frac{\left| \begin{pmatrix} 3 \\ -16 \\ 7 \end{pmatrix} \cdot \begin{pmatrix} 3 \\ 8 \\ -5 \end{pmatrix} \right|}{\sqrt{9+256+49}\sqrt{9+64+25}} = \frac{|9-128-35|}{\sqrt{314}\sqrt{98}} = \frac{154}{\sqrt{314 \times 98}}$$

$$\therefore \theta \approx 28.6^\circ$$

b Since $L_1 \perp L_3$, $\begin{pmatrix} 3 \\ -16 \\ 7 \end{pmatrix} \cdot \begin{pmatrix} 0 \\ -3 \\ x \end{pmatrix} = 0$

$$\begin{aligned} \therefore 48 + 7x &= 0 \\ \therefore x &= -\frac{48}{7} \end{aligned}$$

5 a $x - y = 3$ has gradient $+\frac{1}{1}$ and so has direction vector $\begin{pmatrix} 1 \\ 1 \end{pmatrix}$.

$3x + 2y = 11$ has gradient $-\frac{3}{2}$ and so

has direction vector $\begin{pmatrix} 2 \\ -3 \end{pmatrix}$.

$$\therefore \begin{pmatrix} 1 \\ 1 \end{pmatrix} \cdot \begin{pmatrix} 2 \\ -3 \end{pmatrix} = \sqrt{1+1}\sqrt{4+9} \cos \theta$$

$$\therefore 2 - 3 = \sqrt{2}\sqrt{13} \cos \theta$$

$$\therefore \frac{-1}{\sqrt{26}} = \cos \theta$$

$$\therefore \theta \approx 101.3^\circ$$

$$\therefore \text{ the angle is } 180^\circ - 101.3^\circ \approx 78.7^\circ$$

b $y = x + 2$ has gradient $1 = \frac{1}{1}$ and so has direction vector $\begin{pmatrix} 1 \\ 1 \end{pmatrix}$.

$y = 1 - 3x$ has gradient $-3 = \frac{-3}{1}$ and

so has direction vector $\begin{pmatrix} 1 \\ -3 \end{pmatrix}$.

$$\therefore \begin{pmatrix} 1 \\ 1 \end{pmatrix} \cdot \begin{pmatrix} 1 \\ -3 \end{pmatrix} = \sqrt{1+1}\sqrt{1+9} \cos \theta$$

$$\therefore 1 - 3 = \sqrt{2}\sqrt{10} \cos \theta$$

$$\therefore \frac{-2}{\sqrt{20}} = \cos \theta$$

$$\therefore \theta \approx 116.6^\circ$$

$$\therefore \text{ the angle is } 180^\circ - 116.6^\circ \approx 63.4^\circ$$

c $y + x = 7$ has gradient $-1 = \frac{-1}{1}$ and so has direction vector $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$.

$x - 3y + 2 = 0$ has gradient $\frac{1}{3}$ and so has direction vector $\begin{pmatrix} 3 \\ 1 \end{pmatrix}$.

$$\therefore \begin{pmatrix} 1 \\ -1 \end{pmatrix} \cdot \begin{pmatrix} 3 \\ 1 \end{pmatrix} = \sqrt{1+1}\sqrt{9+1}\cos\theta$$

$$\therefore 3 - 1 = \sqrt{2}\sqrt{10}\cos\theta$$

$$\therefore \frac{2}{\sqrt{20}} = \cos\theta$$

$$\therefore \theta \approx 63.4^\circ$$

$\therefore$ the angle is 63.4° .

d $y = 2 - x$ has gradient $-1 = \frac{-1}{1}$ and so has direction vector $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$.

$x - 2y = 7$ has gradient $\frac{1}{2}$ and so has direction vector $\begin{pmatrix} 2 \\ 1 \end{pmatrix}$.

$$\therefore \begin{pmatrix} 1 \\ -1 \end{pmatrix} \cdot \begin{pmatrix} 2 \\ 1 \end{pmatrix} = \sqrt{1+1}\sqrt{4+1}\cos\theta$$

$$\therefore 2 - 1 = \sqrt{2}\sqrt{5}\cos\theta$$

$$\therefore \frac{1}{\sqrt{10}} = \cos\theta$$

$$\therefore \theta \approx 71.6^\circ$$

$\therefore$ the angle is 71.6° .

EXERCISE 15E

1 a $x(0) = 1$ and $y(0) = 2$,
 $\therefore$ the initial position is $(1, 2)$

c The velocity vector is $\begin{pmatrix} 2 \\ -5 \end{pmatrix}$.

d In 1 second, the x -step is 2 and y -step is -5 ,
which is a distance of $\sqrt{2^2 + (-5)^2} = \sqrt{29}$ cm
 $\therefore$ the speed is $\sqrt{29}$ cm s $^{-1}$.

2 a $\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 2 \\ 3 \end{pmatrix} + t \begin{pmatrix} 4 \\ -5 \end{pmatrix}, t \geq 0$

b 90 minutes = 1.5 hours
When $t = 1.5$, $x = 2 + 4(1.5) = 8$
and $y = 3 - 5(1.5) = -4.5$
 $\therefore$ the boat is at $(8, -4.5)$ after 90 minutes.

c When the boat reaches the point $(5, -0.75)$,
 $2 + 4t = 5$ and $3 - 5t = -0.75$
 $\therefore 4t = 3$ and $-5t = -3.75$
 $\therefore t = 0.75$ and $t = 0.75$
It will take 0.75 hours = 45 minutes for the boat to reach point $(5, -0.75)$.

3 a $\mathbf{r} = \mathbf{a} + t\mathbf{b}$
 $\therefore \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} -3 \\ -2 \end{pmatrix} + t \begin{pmatrix} 2 \\ 4 \end{pmatrix}, t \geq 0$

$$\therefore \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} -3 + 2t \\ -2 + 4t \end{pmatrix}$$

b At $t = 2.5$, $-3 + 2t = -3 + 5 = 2$
and $-2 + 4t = -2 + 10 = 8$

So, the position vector is $\begin{pmatrix} 2 \\ 8 \end{pmatrix}$.

c i When the car is due north, $x = 0$
 $\therefore -3 + 2t = 0$
 $\therefore t = 1.5$ seconds

ii When the car is due west, $y = 0$
 $\therefore -2 + 4t = 0$
 $\therefore t = 0.5$ seconds

- 4 a i** When $t = 0$, $\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} -4 \\ 3 \end{pmatrix}$ **ii** The velocity vector is $\begin{pmatrix} 12 \\ 5 \end{pmatrix}$.
 $\therefore$ the object is at $(-4, 3)$.
iii The speed is $\sqrt{12^2 + 5^2} = 13 \text{ m s}^{-1}$
- b i** When $t = 0$, $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 3 \\ 0 \\ 4 \end{pmatrix}$ **ii** The velocity vector is $\begin{pmatrix} 2 \\ -1 \\ -2 \end{pmatrix}$.
 $\therefore$ the object is at $(3, 0, 4)$.
iii The speed is $\sqrt{2^2 + (-1)^2 + (-2)^2} = 3 \text{ m s}^{-1}$
- 5 a** $\begin{pmatrix} 4 \\ -3 \end{pmatrix}$ has length $\sqrt{4^2 + (-3)^2} = 5$ **b** $2\mathbf{i} + \mathbf{j} = \begin{pmatrix} 2 \\ 1 \end{pmatrix}$ has length $\sqrt{2^2 + 1^2} = \sqrt{5}$
 $\therefore 30 \begin{pmatrix} 4 \\ -3 \end{pmatrix}$ has length 150 $\therefore 10\sqrt{5} \begin{pmatrix} 2 \\ 1 \end{pmatrix}$ has length 50
 $\therefore$ the velocity vector is $\begin{pmatrix} 120 \\ -90 \end{pmatrix}$. $\therefore$ the velocity vector is $\begin{pmatrix} 20\sqrt{5} \\ 10\sqrt{5} \end{pmatrix}$.
- 6** $-2\mathbf{i} + 5\mathbf{j} - 14\mathbf{k}$ has length $\sqrt{(-2)^2 + 5^2 + (-14)^2} = \sqrt{4 + 25 + 196} = \sqrt{225} = 15$
 $\therefore 6 \begin{pmatrix} -2 \\ 5 \\ -14 \end{pmatrix}$ has length 90, so the velocity vector is $\begin{pmatrix} -12 \\ 30 \\ -84 \end{pmatrix}$.
- 7** Yacht A: $\begin{pmatrix} x_A \\ y_A \end{pmatrix} = \begin{pmatrix} 4 \\ 5 \end{pmatrix} + t \begin{pmatrix} 1 \\ -2 \end{pmatrix}$ Yacht B: $\begin{pmatrix} x_B \\ y_B \end{pmatrix} = \begin{pmatrix} 1 \\ -8 \end{pmatrix} + t \begin{pmatrix} 2 \\ 3 \end{pmatrix}, t \geq 0$
a When $t = 0$, $\begin{pmatrix} x_A \\ y_A \end{pmatrix} = \begin{pmatrix} 4 \\ 5 \end{pmatrix} \therefore$ A is at $(4, 5)$
and $\begin{pmatrix} x_B \\ y_B \end{pmatrix} = \begin{pmatrix} 1 \\ -8 \end{pmatrix} \therefore$ B is at $(1, -8)$.
b For A, the velocity vector is $\begin{pmatrix} 1 \\ -2 \end{pmatrix}$, and for B it is $\begin{pmatrix} 2 \\ 1 \end{pmatrix}$.
c Speed of A = $\sqrt{1^2 + (-2)^2} = \sqrt{5} \text{ km h}^{-1}$. Speed of B = $\sqrt{2^2 + 1^2} = \sqrt{5} \text{ km h}^{-1}$.
d A has direction vector $\begin{pmatrix} 1 \\ -2 \end{pmatrix}$ and B has direction vector $\begin{pmatrix} 2 \\ 1 \end{pmatrix}$.
Since $\begin{pmatrix} 1 \\ -2 \end{pmatrix} \bullet \begin{pmatrix} 2 \\ 1 \end{pmatrix} = 2 - 2 = 0$, the paths of the yachts are at right angles to each other.
- 8 a** P's torpedo has position $\begin{pmatrix} x_1 \\ y_1 \end{pmatrix} = \begin{pmatrix} -5 \\ 4 \end{pmatrix} + t \begin{pmatrix} 3 \\ -1 \end{pmatrix}$ and at $t = 0$, the time is 1:34 pm
 $\therefore x_1(t) = -5 + 3t, y_1(t) = 4 - t$.
b Speed = $\sqrt{3^2 + (-1)^2} = \sqrt{10} \text{ km min}^{-1}$
c Q fires its torpedo after a minutes.
 $\therefore$ at time t , its torpedo has travelled for $(t - a)$ minutes.
 $\therefore \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} = \begin{pmatrix} 15 \\ 7 \end{pmatrix} + (t - a) \begin{pmatrix} -4 \\ -3 \end{pmatrix}, t \geq a$
 $\therefore x_2(t) = 15 - 4(t - a)$ and $y_2(t) = 7 - 3(t - a)$
 $\therefore$ position is Q($15 - 4(t - a), 7 - 3(t - a)$).

- d** They meet when $x_1(t) = x_2(t)$ and $y_1(t) = y_2(t)$
 $\therefore -5 + 3t = 15 - 4(t - a)$ and $4 - t = 7 - 3(t - a)$
 $\therefore 7t - 4a = 20 \dots (1)$ and $2t - 3a = 3 \dots (2)$
 Solving simultaneously,
$$\begin{array}{rcl} 21t - 12a = 60 & \{3 \times (1)\} \\ -8t + 12a = -12 & \{-4 \times (2)\} \\ \hline \text{adding} & 13t & = 48 \end{array}$$

 $\therefore t = \frac{48}{13}$ and $7\left(\frac{48}{13}\right) - 4a = 20$
 $\therefore t \approx 3.6923$ $\therefore 5.8462 = 4a$
 $\therefore t \approx 3 \text{ min } 41.54 \text{ sec}$ $\therefore a \approx 1.4615 \approx 1 \text{ min } 27.7 \text{ sec}$

So, as $a \approx 1.4615$, Q fired at 1:35:28 pm, and the explosion occurred at 1:37:42 pm.

- 9 a** $\overrightarrow{AB} = \begin{pmatrix} 3-6 \\ 10-9 \\ 2.5-3 \end{pmatrix} = \begin{pmatrix} -3 \\ 1 \\ -0.5 \end{pmatrix}$ **b** $|\overrightarrow{AB}| = \sqrt{(-3)^2 + 1^2 + (-0.5)^2}$
 $= \sqrt{10.25} \text{ km}$
c $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 6 \\ 9 \\ 3 \end{pmatrix} + t \begin{pmatrix} -3 \\ 1 \\ -0.5 \end{pmatrix}, t \in \mathbb{R}$ The helicopter travels $\sqrt{10.25} \text{ km}$ in 10 minutes.
 $\therefore$ the helicopter's speed is
 $6 \times \sqrt{10.25} \approx 19.2 \text{ km h}^{-1}$.
d If $z = 0$, $3 + (-0.5)t = 0$
 $\therefore t = 6$
 $t = 1$ represents 10 minutes, so $t = 6$ represents 60 minutes.
 $\therefore$ the helicopter lands on the helipad after 1 hour.

EXERCISE 15F

- 1 a** Let N be the point on the line closest to P.
 N has coordinates $(2 + t, 3 + 2t)$ for some $t \in \mathbb{R}$.
 $\overrightarrow{PN}$ is $\begin{pmatrix} 2+t-3 \\ 3+2t-2 \end{pmatrix} = \begin{pmatrix} t-1 \\ 2t+1 \end{pmatrix}$.
 Now $\overrightarrow{PN} \bullet \begin{pmatrix} 1 \\ 2 \end{pmatrix} = 0$, as $\begin{pmatrix} 1 \\ 2 \end{pmatrix}$ is the direction vector of the line.
 $\therefore \begin{pmatrix} t-1 \\ 2t+1 \end{pmatrix} \bullet \begin{pmatrix} 1 \\ 2 \end{pmatrix} = 0$
 $\therefore (t-1) + 2(2t+1) = 0$
 $\therefore t-1+4t+2=0$
 $\therefore 5t = -1$
 $\therefore t = -\frac{1}{5}$
 Thus $\overrightarrow{PN} = \begin{pmatrix} -\frac{1}{5}-1 \\ -\frac{2}{5}+1 \end{pmatrix} = \begin{pmatrix} -\frac{6}{5} \\ \frac{3}{5} \end{pmatrix}$
 $= \frac{3}{5} \begin{pmatrix} -2 \\ 1 \end{pmatrix}$
 and $|\overrightarrow{PN}| = \frac{3}{5} \left| \begin{pmatrix} -2 \\ 1 \end{pmatrix} \right| = \frac{3}{5} \sqrt{(-2)^2 + 1^2}$
 $= \frac{3}{5} \sqrt{5}$
 So the shortest distance from P to the line is $\frac{3}{5} \sqrt{5}$ units.
- b** Let N be the point on the line closest to Q.
 N has coordinates $(t, 1-t)$ for some $t \in \mathbb{R}$.
 $\overrightarrow{QN}$ is $\begin{pmatrix} t-(-1) \\ 1-t-1 \end{pmatrix} = \begin{pmatrix} t+1 \\ -t \end{pmatrix}$.
 Now $\overrightarrow{QN} \bullet \begin{pmatrix} 1 \\ -1 \end{pmatrix} = 0$, as $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$ is the direction vector of the line.
 $\therefore \begin{pmatrix} t+1 \\ -t \end{pmatrix} \bullet \begin{pmatrix} 1 \\ -1 \end{pmatrix} = 0$
 $\therefore (t+1) + (-1)(-t) = 0$
 $\therefore t+1+t=0$
 $\therefore 2t = -1$
 $\therefore t = -\frac{1}{2}$
 Thus $\overrightarrow{QN} = \begin{pmatrix} -\frac{1}{2}+1 \\ -(-\frac{1}{2}) \end{pmatrix} = \begin{pmatrix} \frac{1}{2} \\ \frac{1}{2} \end{pmatrix}$
 $= \frac{1}{2} \begin{pmatrix} 1 \\ 1 \end{pmatrix}$
 and $|\overrightarrow{QN}| = \frac{1}{2} \left| \begin{pmatrix} 1 \\ 1 \end{pmatrix} \right| = \frac{1}{2} \sqrt{1^2 + 1^2}$
 $= \frac{1}{2} \sqrt{2}$
 So the shortest distance from Q to the line is $\frac{1}{2} \sqrt{2}$ units.

- c** Let N be the point on the line closest to R.
N has coordinates $(2 + s, 3 - s)$ for some $s \in \mathbb{R}$.

$$\overrightarrow{RN} \text{ is } \begin{pmatrix} 2 + s - (-3) \\ 3 - s - (-1) \end{pmatrix} = \begin{pmatrix} s + 5 \\ 4 - s \end{pmatrix}.$$

Now $\overrightarrow{RN} \bullet \begin{pmatrix} 1 \\ -1 \end{pmatrix} = 0$, as $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$ is the direction vector of the line.

$$\therefore \begin{pmatrix} s + 5 \\ 4 - s \end{pmatrix} \bullet \begin{pmatrix} 1 \\ -1 \end{pmatrix} = 0$$

$$\therefore (s + 5) + (-1)(4 - s) = 0$$

$$\therefore s + 5 - 4 + s = 0$$

$$\therefore 2s = -1$$

$$\therefore s = -\frac{1}{2}$$

$$\begin{aligned} \text{Thus } \overrightarrow{RN} &= \begin{pmatrix} -\frac{1}{2} + 5 \\ 4 - (-\frac{1}{2}) \end{pmatrix} = \begin{pmatrix} \frac{9}{2} \\ \frac{9}{2} \end{pmatrix} \\ &= \frac{9}{2} \begin{pmatrix} 1 \\ 1 \end{pmatrix} \end{aligned}$$

$$\begin{aligned} \text{and } |\overrightarrow{RN}| &= \frac{9}{2} \left| \begin{pmatrix} 1 \\ 1 \end{pmatrix} \right| = \frac{9}{2} \sqrt{1^2 + 1^2} \\ &= \frac{9}{2} \sqrt{2} \end{aligned}$$

So the shortest distance from R to the line is $\frac{9}{2}\sqrt{2}$ units.

- d** Let N be the point on the line closest to S.
N has coordinates $(2 + 3t, 5 - 7t)$ for some $t \in \mathbb{R}$.

$$\overrightarrow{SN} \text{ is } \begin{pmatrix} 2 + 3t - 5 \\ 5 - 7t - (-2) \end{pmatrix} = \begin{pmatrix} 3t - 3 \\ 7 - 7t \end{pmatrix}.$$

Now $\overrightarrow{SN} \bullet \begin{pmatrix} 3 \\ -7 \end{pmatrix} = 0$, as $\begin{pmatrix} 3 \\ -7 \end{pmatrix}$ is the direction vector of the line.

$$\therefore \begin{pmatrix} 3t - 3 \\ 7 - 7t \end{pmatrix} \bullet \begin{pmatrix} 3 \\ -7 \end{pmatrix} = 0$$

$$\therefore 3(3t - 3) - 7(7 - 7t) = 0$$

$$\therefore 9t - 9 - 49 + 49t = 0$$

$$\therefore 58t = -58$$

$$\therefore t = -1$$

$$\text{Thus } \overrightarrow{SN} = \begin{pmatrix} 3(-1) - 3 \\ 7 - 7(-1) \end{pmatrix} = \begin{pmatrix} -6 \\ 14 \end{pmatrix}$$

$$\therefore |\overrightarrow{SN}| = 0$$

So S actually lies on the line, and the shortest distance is 0 units.

2 a $6\mathbf{i} - 6\mathbf{j}$

- b** The length of $\begin{pmatrix} -3 \\ 4 \end{pmatrix} = \sqrt{(-3)^2 + 4^2} = \sqrt{25} = 5$

As the speed is 10 km h^{-1} , the liner has velocity vector $2 \begin{pmatrix} -3 \\ 4 \end{pmatrix} = \begin{pmatrix} -6 \\ 8 \end{pmatrix}$.

$\therefore$ the liner has position $\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 6 \\ -6 \end{pmatrix} + t \begin{pmatrix} -6 \\ 8 \end{pmatrix} = \begin{pmatrix} 6 - 6t \\ -6 + 8t \end{pmatrix}$, $t \geq 0$, t in hours.

- c** The liner is due east when $y = 0$
 $\therefore -6 + 8t = 0$
 $\therefore$ at $t = \frac{3}{4}$ hours

- d** The liner L is nearest the fishing boat O when $\overrightarrow{OL} \perp \begin{pmatrix} -3 \\ 4 \end{pmatrix}$

$$\therefore \overrightarrow{OL} \bullet \begin{pmatrix} -3 \\ 4 \end{pmatrix} = 0$$

$$\therefore \begin{pmatrix} 6 - 6t \\ -6 + 8t \end{pmatrix} \bullet \begin{pmatrix} -3 \\ 4 \end{pmatrix} = 0$$

$$\therefore (-18 + 18t) + (-24 + 32t) = 0$$

$$\therefore 50t = 42$$

$$\therefore t = 0.84 \text{ hours} = 50.4 \text{ minutes}$$

$$\text{and when } t = 0.84, \overrightarrow{OL} = \begin{pmatrix} 6 - 6(0.84) \\ -6 + 8(0.84) \end{pmatrix} = \begin{pmatrix} 0.96 \\ 0.72 \end{pmatrix}$$

$\therefore$ the liner is closest to the fishing boat after 0.84 hours or 50.4 minutes, when it is at $(0.96, 0.72)$.

3 a $|\mathbf{b}| = \sqrt{(-3)^2 + (-1)^2} = \sqrt{10}$

As the speed is $40\sqrt{10} \text{ km h}^{-1}$, the velocity vector is $40 \begin{pmatrix} -3 \\ -1 \end{pmatrix} = \begin{pmatrix} -120 \\ -40 \end{pmatrix}$.

b $\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 200 \\ 100 \end{pmatrix} + t \begin{pmatrix} -120 \\ -40 \end{pmatrix}, \quad t \geq 0 \quad \{t = 0 \text{ at } 12:00 \text{ noon}\}$

c At 1:00 pm, $t = 1$ and $\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 200 - 120 \\ 100 - 40 \end{pmatrix} = \begin{pmatrix} 80 \\ 60 \end{pmatrix}$
 $\therefore$ the aircraft is at (80, 60).

d The distance from $O(0, 0)$ to $P_1(80, 60)$ is $\left| \begin{pmatrix} 80 \\ 60 \end{pmatrix} \right| = \sqrt{80^2 + 60^2} = 100 \text{ km}$,
 which is when it becomes visible to radar. {within 100 km of $O(0, 0)$ }

A general point on the path is $P(200 - 120t, 100 - 40t)$.

Now $\overrightarrow{OP} = \begin{pmatrix} 200 - 120t \\ 100 - 40t \end{pmatrix}$,

and for the closest point $\overrightarrow{OP} \cdot \begin{pmatrix} -3 \\ -1 \end{pmatrix} = 0$

$\therefore -3(200 - 120t) - 1(100 - 40t) = 0$

$\therefore -700 + 400t = 0$

$\therefore t = \frac{7}{4} = 1\frac{3}{4} \text{ hours}$

$\therefore$ the time when the aircraft is closest is 1:45 pm, and

at this time $\overrightarrow{OP} = \begin{pmatrix} 200 - 120(\frac{7}{4}) \\ 100 - 40(\frac{7}{4}) \end{pmatrix} = \begin{pmatrix} -10 \\ 30 \end{pmatrix}$

$\therefore d_{\min} = \sqrt{(-10)^2 + 30^2} \approx 31.6 \text{ km}$

f It disappears from radar when $|\overrightarrow{OP}| = 100$ and $t > 1\frac{3}{4}$

$\therefore \sqrt{(200 - 120t)^2 + (100 - 40t)^2} = 100$

$\therefore 40\,000 - 48\,000t + 14\,400t^2 + 10\,000 - 8\,000t + 1600t^2 = 10\,000$

$\therefore 16\,000t^2 - 56\,000t + 40\,000 = 0$

$\therefore 16t^2 - 56t + 40 = 0 \quad \{\div 1000\}$

$\therefore 2t^2 - 7t + 5 = 0 \quad \{\div 8\}$

$\therefore (2t - 5)(t - 1) = 0$

$\therefore t = \frac{5}{2} \quad \{\text{as } t > 1\frac{3}{4}\}$

So, the aircraft disappears from the radar screen $2\frac{1}{2}$ hours after noon, or at 2:30 pm.

4 a At A, $y = 0$ At B, $x = 0$
 $\therefore 2x = 36$ $\therefore 3y = 36$
 $\therefore x = 18$ $\therefore y = 12$
 So A is (18, 0) and B is (0, 12).

b $2x + 3y = 36$
 $\therefore 3y = 36 - 2x$
 $\therefore y = \frac{36 - 2x}{3}$

$\therefore$ any point R on the railway track can be written $R\left(x, \frac{36 - 2x}{3}\right)$.

c $\overrightarrow{PR} = \begin{pmatrix} x - 4 \\ \frac{36 - 2x}{3} - 0 \end{pmatrix} = \begin{pmatrix} x - 4 \\ \frac{36 - 2x}{3} \end{pmatrix}$,
 $\overrightarrow{AB} = \begin{pmatrix} 0 - 18 \\ 12 - 0 \end{pmatrix} = \begin{pmatrix} -18 \\ 12 \end{pmatrix}$

- d** The point closest to the railway track is R such that $\overrightarrow{PR} \perp \overrightarrow{AB}$.

$$\therefore \overrightarrow{PR} \cdot \overrightarrow{AB} = 0$$

$$\therefore \begin{pmatrix} x-4 \\ \frac{36-2x}{3} \end{pmatrix} \cdot \begin{pmatrix} -18 \\ 12 \end{pmatrix} = 0$$

$$\therefore -18(x-4) + 4(36-2x) = 0$$

$$\therefore -18x + 72 + 144 - 8x = 0$$

$$\therefore 26x = 216$$

$$\therefore x = \frac{108}{13}$$

Now when $x = \frac{108}{13}$, $\frac{36-2x}{3} = 12 - \frac{2}{3}x = 12 - \frac{2}{3}\left(\frac{108}{13}\right) = \frac{84}{13}$. So R is $\left(\frac{108}{13}, \frac{84}{13}\right)$.

$$|\overrightarrow{PR}| = \sqrt{\left(\frac{108}{13} - 4\right)^2 + \left(\frac{84}{13} - 0\right)^2} = \sqrt{\frac{784}{13}} \approx 7.77 \text{ km}$$

The closest point on the track to the camp is $\left(\frac{108}{13}, \frac{84}{13}\right)$, a distance of 7.77 km.

- 5** For A, $x_A(t) = 3 - t$, $y_A(t) = 2t - 4$ For B, $x_B(t) = 4 - 3t$, $y_B(t) = 3 - 2t$

- a** When $t = 0$, $x_A(0) = 3$, $y_A(0) = -4$ and $x_B(0) = 4$, $y_B(0) = 3$
 $\therefore$ A is at $(3, -4)$. $\therefore$ B is at $(4, 3)$.

- b** The velocity vector of A is $\begin{pmatrix} -1 \\ 2 \end{pmatrix}$ and the velocity vector of B is $\begin{pmatrix} -3 \\ -2 \end{pmatrix}$.

- c** If the angle is θ , $\begin{pmatrix} -1 \\ 2 \end{pmatrix} \cdot \begin{pmatrix} -3 \\ -2 \end{pmatrix} = \sqrt{1+4}\sqrt{9+4}\cos\theta$

$$\therefore 3 - 4 = \sqrt{5}\sqrt{13}\cos\theta$$

$$\therefore \frac{-1}{\sqrt{65}} = \cos\theta \text{ and so } \theta \approx 97.1^\circ$$

$\therefore$ the acute angle between the paths is $\approx 82.9^\circ$.

- d** If D is the distance between them, then

$$\begin{aligned} D &= \sqrt{[(4-3t) - (3-t)]^2 + [(3-2t) - (2t-4)]^2} \\ &= \sqrt{[1-2t]^2 + [7-4t]^2} \\ &= \sqrt{1-4t+4t^2+49-56t+16t^2} \\ &= \sqrt{20t^2-60t+50} \end{aligned}$$

$\therefore$ the boats are closest after $1\frac{1}{2}$ hours.

Under the square root we have a quadratic in t , so D is a minimum when

$$t = -\frac{b}{2a} = \frac{60}{40} = 1\frac{1}{2}$$

$\therefore t = 1.5$ hours

- 6 a** The direction vector of the line is $\mathbf{b} = \begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}$.

Let the point $(3, 0, -1)$ be P, and $A(2+3t, -1+2t, 4+t)$ be any point on the line.

$$\therefore \overrightarrow{PA} = \begin{pmatrix} 2+3t-3 \\ -1+2t-0 \\ 4+t-(-1) \end{pmatrix} = \begin{pmatrix} -1+3t \\ -1+2t \\ 5+t \end{pmatrix}$$

Now $\overrightarrow{PA}$ and $\mathbf{b}$ are perpendicular, so $\overrightarrow{PA} \cdot \mathbf{b} = 0$.

$$\therefore \begin{pmatrix} -1+3t \\ -1+2t \\ 5+t \end{pmatrix} \cdot \begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix} = 0$$

$$\therefore -3 + 9t - 2 + 4t + 5 + t = 0$$

$$\therefore 14t = 0$$

$$\therefore t = 0$$

Substituting $t = 0$ into the parametric equations, we obtain the foot of the perpendicular $(2, -1, 4)$.

b When $t = 0$, $\vec{PA} = \begin{pmatrix} -1 \\ -1 \\ 5 \end{pmatrix}$, so $PA = \sqrt{1 + 1 + 25}$
 $= \sqrt{27}$ units

$\therefore$ the shortest distance from the point to the line is $\sqrt{27}$ units.

7 a The line has direction vector $\mathbf{b} = \begin{pmatrix} 2 \\ 3 \\ 1 \end{pmatrix}$.

Let the point $(1, 1, 3)$ be P and $A(1 + 2t, -1 + 3t, 2 + t)$ be any point on the line.

$$\therefore \vec{PA} = \begin{pmatrix} 1 + 2t - 1 \\ -1 + 3t - 1 \\ 2 + t - 3 \end{pmatrix} = \begin{pmatrix} 2t \\ -2 + 3t \\ -1 + t \end{pmatrix}.$$

Now $\vec{PA}$ and $\mathbf{b}$ are perpendicular, so $\vec{PA} \bullet \mathbf{b} = 0$

$$\begin{aligned} \therefore \begin{pmatrix} 2t \\ -2 + 3t \\ -1 + t \end{pmatrix} \bullet \begin{pmatrix} 2 \\ 3 \\ 1 \end{pmatrix} &= 0 \\ \therefore 4t - 6 + 9t - 1 + t &= 0 \\ \therefore 14t &= 7 \\ \therefore t &= \frac{1}{2} \end{aligned}$$

Substituting $t = \frac{1}{2}$ into the parametric equations, we obtain the foot of the perpendicular $(2, \frac{1}{2}, \frac{5}{2})$.

b When $t = \frac{1}{2}$, $\vec{PA} = \begin{pmatrix} 1 \\ -2 + \frac{3}{2} \\ -1 + \frac{1}{2} \end{pmatrix} = \begin{pmatrix} 1 \\ -\frac{1}{2} \\ -\frac{1}{2} \end{pmatrix}$

$$\therefore PA = \sqrt{1 + \frac{1}{4} + \frac{1}{4}} = \sqrt{\frac{3}{2}} \text{ units}$$

$\therefore$ the shortest distance from the point to the line is $\sqrt{\frac{3}{2}}$ units.

So, the solution is $x = 2, y = -3$.

- b** In augmented matrix form, the system is:

$$\left[\begin{array}{cc|c} 4 & 5 & 21 \\ 5 & -3 & -20 \end{array} \right] \sim \left[\begin{array}{cc|c} 4 & 5 & 21 \\ 0 & -37 & -185 \end{array} \right] \quad R_2 \rightarrow 4R_2 - 5R_1$$

$$\begin{array}{ccc} 20 & -12 & -80 \\ -20 & -25 & -105 \\ \hline 0 & -37 & -185 \end{array}$$

$$\text{From } R_2, \quad -37y = -185$$

$$\therefore y = 5$$

$$\text{Now } 4x + 5y = 21$$

$$\therefore 4x + 25 = 21$$

$$\therefore 4x = -4$$

$$\therefore x = -1$$

So, the solution is $x = -1, y = 5$.

- c** In augmented matrix form, the system is:

$$\left[\begin{array}{cc|c} 3 & 1 & -10 \\ 2 & 5 & -24 \end{array} \right] \sim \left[\begin{array}{cc|c} 3 & 1 & -10 \\ 0 & 13 & -52 \end{array} \right] \quad R_2 \rightarrow 3R_2 - 2R_1$$

$$\begin{array}{ccc} 6 & 15 & -72 \\ -6 & -2 & 20 \\ \hline 0 & 13 & -52 \end{array}$$

$$\text{From } R_2, \quad 13y = -52$$

$$\therefore y = -4$$

$$\text{Now } 3x + y = -10$$

$$\therefore 3x + (-4) = -10$$

$$\therefore 3x = -6$$

$$\therefore x = -2$$

So, the solution is $x = -2, y = -4$.

- 2 a** One equation is not a multiple of the other and their gradients are not the same, so the lines are intersecting.
- b** $x + y = 7$ can be written as $3x + 3y = 21$ and the other line is $3x + 3y = 1$,
 $\therefore$ the lines are parallel.
- c** The lines intersect at $(2\frac{1}{2}, 2)$.
- d** $x - 2y = 4$ can be written as $2x - 4y = 8$, so the lines are coincident.
- e** The lines are intersecting.
- f** $3x - 4y = 5$ can be written as $-3x + 4y = -5$ and the other line is $-3x + 4y = 2$,
 $\therefore$ the lines are parallel.
- 3 a** $x + 2y = 3$ can be written as $2x + 4y = 6$, $\therefore$ the equations represent coincident lines.
 So, there are an infinite number of solutions (all the points on the line).

- b** As the second equation is an exact multiple of the first, it will give the same solutions as the first so it can be ignored.

- c** **i** If $x = t$, $t + 2y = 3$
 $\therefore 2y = 3 - t$
 $\therefore y = \frac{3-t}{2}$ $\therefore$ the solutions are $x = t$, $y = \frac{3-t}{2}$, $t \in \mathbb{R}$.
- ii** If $y = s$, $x + 2s = 3$
 $\therefore x = 3 - 2s$ $\therefore$ the solutions are $x = 3 - 2s$, $y = s$, $s \in \mathbb{R}$.

- 4 a** In augmented matrix form, the system is:

$$\left[\begin{array}{cc|c} 2 & 3 & 5 \\ 2 & 3 & 11 \end{array} \right] \sim \left[\begin{array}{cc|c} 2 & 3 & 5 \\ 0 & 0 & 6 \end{array} \right] R_2 \rightarrow R_2 - R_1$$

$$\begin{array}{ccc} 2 & 3 & 11 \\ -2 & -3 & -5 \\ \hline 0 & 0 & 6 \end{array}$$

- b** R_2 shows $0x + 0y = 6$ $\therefore$ there are no solutions **c** the lines are parallel

- 5 a** In augmented matrix form, the system is:

$$\left[\begin{array}{cc|c} 2 & 3 & 5 \\ 4 & 6 & 10 \end{array} \right] \sim \left[\begin{array}{cc|c} 2 & 3 & 5 \\ 0 & 0 & 0 \end{array} \right] R_2 \rightarrow R_2 - 2R_1$$

$$\begin{array}{ccc} 4 & 6 & 10 \\ -4 & -6 & -10 \\ \hline 0 & 0 & 0 \end{array}$$

- b** R_2 shows $0x + 0y = 0$, which is true for all x and y .

All solutions come from $2x + 3y = 5$. Let $x = t$, $y = \frac{5-2t}{3}$ for all values of t

$\therefore$ there are infinitely many solutions of the form $x = t$, $y = \frac{5-2t}{3}$, $t \in \mathbb{R}$.

The lines are coincident.

- 6 a** In augmented matrix form, the system is:

$$\left[\begin{array}{cc|c} 3 & -1 & 2 \\ 6 & -2 & 4 \end{array} \right] \sim \left[\begin{array}{cc|c} 3 & -1 & 2 \\ 0 & 0 & 0 \end{array} \right] R_2 \rightarrow R_2 - 2R_1$$

$$\begin{array}{ccc} 6 & -2 & 4 \\ -6 & 2 & -4 \\ \hline 0 & 0 & 0 \end{array}$$

R_2 shows $0x + 0y = 0$, which is true for all x and y .

So, there are infinitely many solutions {the lines are coincident}.

Substitute $x = t$ in the first equation $3x - y = 2$

$$\therefore 3t - y = 2$$

$$y = 3t - 2$$

So, the solutions have form $x = t$, $y = 3t - 2$, $t \in \mathbb{R}$.

- b** $3x - y = 2$ (1)

$$6x - 2y = k \text{ (2)}$$

If $k = 4$ then $6x - 2y = 4$, which is an exact multiple ($\times 2$) of equation (1), $\therefore$ the lines are coincident and there are an infinite number of solutions of the form $x = t$, $y = 3t - 2$, $t \in \mathbb{R}$.

If $k \neq 4$ then the equations represent parallel lines $\therefore$ there are no solutions.

- 7 a** In augmented matrix form, the system is:

$$\left[\begin{array}{cc|c} 3 & -1 & 8 \\ 6 & -2 & k \end{array} \right] \sim \left[\begin{array}{cc|c} 3 & -1 & 8 \\ 0 & 0 & k-16 \end{array} \right] R_2 \rightarrow R_2 - 2R_1$$

$$\begin{array}{ccc} 6 & -2 & k \\ -6 & 2 & -16 \\ \hline 0 & 0 & k-16 \end{array}$$

- b** **i** If $k = 16$ there are infinitely many solutions.

- ii** Substitute $x = t$ in $3x - y = 8$, then $3t - y = 8$ $\therefore y = 3t - 8$.
 The solutions are $x = t$, $y = 3t - 8$, $t \in \mathbb{R}$.

- c** **i** The system has no solutions when $k - 16 \neq 0$, $\therefore k \neq 16$.

- ii** The lines are parallel but not coincident.

- 8 a In augmented matrix form, the system is:

$$\begin{aligned} \left[\begin{array}{cc|c} 4 & 8 & 1 \\ 2 & -a & 11 \end{array} \right] &\sim \left[\begin{array}{cc|c} 4 & 8 & 1 \\ 0 & -2a-8 & 21 \end{array} \right] & R_2 \rightarrow 2R_2 - R_1 & \begin{array}{ccc} 4 & -2a & 22 \\ -4 & -8 & -1 \\ \hline 0 & -2a-8 & 21 \end{array} \\ &\sim \left[\begin{array}{cc|c} 4 & 8 & 1 \\ 0 & 2a+8 & -21 \end{array} \right] & R_2 \rightarrow -R_2 & \end{aligned}$$

- b A unique solution exists provided $2a+8 \neq 0 \therefore a \neq -4$.

- c From R_2 , $(2a+8)y = -21$

$$\therefore y = \frac{-21}{2a+8} \quad \therefore 4x(2a+8) - 168 = 2a+8$$

$$\therefore 2x(2a+8) - 84 = a+4$$

$$\text{and } 4x+8y=1 \quad \therefore 2x(2a+8) = a+88$$

$$\therefore 4x+8\left(\frac{-21}{2a+8}\right)=1 \quad \therefore x = \frac{a+88}{4a+16}$$

$$\text{The solution is } x = \frac{a+88}{4a+16}, y = \frac{-21}{2a+8}, a \neq -4.$$

- d When $a = -4$ there are no solutions as the lines are parallel.

- 9 a In augmented matrix form, the system is:

$$\begin{aligned} \left[\begin{array}{cc|c} m & 2 & 6 \\ 2 & m & 6 \end{array} \right] &\sim \left[\begin{array}{cc|c} m & 2 & 6 \\ 0 & m^2-4 & 6m-12 \end{array} \right] & R_2 \rightarrow mR_2 - 2R_1 & \begin{array}{ccc} 2m & m^2 & 6m \\ -2m & -4 & -12 \\ \hline 0 & m^2-4 & 6m-12 \end{array} \end{aligned}$$

A unique solution exists provided $m^2 - 4 \neq 0$.

So, there is a unique solution for all m except $m = \pm 2$.

- b In R_2 , $(m^2-4)y = 6m-12$

Substituting in $mx+2y=6$

$$\therefore y = \frac{6(m-2)}{(m-2)(m+2)} \quad \text{gives } mx+2\left(\frac{6}{m+2}\right)=6$$

$$\begin{aligned} \therefore y = \frac{6}{m+2} \quad \text{provided } m \neq \pm 2 &\quad \therefore m(m+2)x+12=6(m+2) \\ &\quad \therefore m(m+2)x=6m+12-12 \\ &\quad \therefore m(m+2)x=6m \\ &\quad \therefore x = \frac{6}{m+2} \end{aligned}$$

So, the unique solution is $x = \frac{6}{m+2}$, $y = \frac{6}{m+2}$ when $m \neq \pm 2$.

- c When $m = 2$, the equations are $2x+2y=6$ and $2x+2y=6$, $\therefore$ the lines are coincident. So, there are an infinite number of solutions of the form $x=t$, $y = \frac{6-2t}{2} = 3-t$ for all $t \in \mathbb{R}$.

When $m = -2$, the equations are $-2x+2y=6$ and $2x-2y=6$
or $-2x+2y=-6$

$\therefore$ the lines are parallel and there are no solutions.

EXERCISE 15H.2

- 1 a Line 1 has direction vector $\begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 3 \\ -1 \\ 2 \end{pmatrix}$.

As one vector is not a scalar multiple of the other, the lines are not parallel.

$$\begin{aligned} \text{Now } 1+2t &= -2+3s & 2-t &= 3-s & 3+t &= 1+2s \\ \therefore 2t-3s &= -3 \quad \dots (1) & \therefore -t+s &= 1 \quad \dots (2) & \therefore t-2s &= -2 \quad \dots (3) \end{aligned}$$

Solving (2) and (3) simultaneously:
$$\begin{array}{rcl} -t + s & = & 1 \\ t - 2s & = & -2 \\ \hline -s & = & -1 \end{array} \therefore s = 1 \text{ and } t = 0$$

and in (1), $\text{LHS} = 2t - 3s = 2(0) - 3(1) = -3 \checkmark$

$\therefore s = 1, t = 0$ satisfies all three equations

$\therefore$ the two lines meet at $(1, 2, 3)$ {using $t = 0$ or $s = 1$ }

The acute angle between the lines has
$$\cos \theta = \frac{|6 + 1 + 2|}{\sqrt{4 + 1 + 1} \sqrt{9 + 1 + 4}} = \frac{9}{\sqrt{84}}$$
 and so $\theta \approx 10.9^\circ$

b Line 1 has direction vector $\begin{pmatrix} 2 \\ -12 \\ 12 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 4 \\ 3 \\ -1 \end{pmatrix}$.

As one vector is not a scalar multiple of the other, the lines are not parallel.

Now $-1 + 2\lambda = 4\mu - 3$ $2 - 12\lambda = 3\mu + 2$ $4 + 12\lambda = -\mu - 1$
 $\therefore 2\lambda - 4\mu = -2$ $-12\lambda - 3\mu = 0$ $12\lambda + \mu = -5 \dots (3)$
 $\therefore \lambda - 2\mu = -1 \dots (1)$ $\mu = -4\lambda \dots (2)$

Solving (1) and (2) simultaneously: $\lambda - 2(-4\lambda) = -1$
 $\therefore 9\lambda = -1$
 $\therefore \lambda = -\frac{1}{9}$ and so $\mu = \frac{4}{9}$

In (3), $12\lambda + \mu = 12\left(-\frac{1}{9}\right) + \frac{4}{9} = -\frac{12}{9} + \frac{4}{9} = -\frac{8}{9}$, which is not -5 .

Since the system is inconsistent, the lines do not intersect, so the lines are skew.

The acute angle between the lines has
$$\cos \theta = \frac{|8 - 36 - 12|}{\sqrt{292} \sqrt{26}} = \frac{40}{\sqrt{7592}}$$
 and so $\theta \approx 62.7^\circ$.

c Line 1 has direction vector $\begin{pmatrix} 6 \\ 8 \\ 2 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 3 \\ 4 \\ 1 \end{pmatrix}$.
 As $\begin{pmatrix} 6 \\ 8 \\ 2 \end{pmatrix} = 2 \begin{pmatrix} 3 \\ 4 \\ 1 \end{pmatrix}$ the two lines are parallel. Hence, $\theta = 0^\circ$.

To see if the lines are coincident, try to find a shared point.

The point on line 1 where $t = 1$ is $(6, 11, 1)$.

The unique point on line 2 with z -coordinate 1 is the point where $1 + s = 1 \therefore s = 0$.

This point is $(2, 0, 1)$. Since $(6, 11, 1) \neq (2, 0, 1)$ the lines are not coincident.

d In line 1 let $x = 2 - y = z + 2 = t$, so $x = t$, $y = 2 - t$, and $z = t - 2$, $t \in \mathbb{R}$.

Line 1 has direction vector $\begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 3 \\ -2 \\ 2 \end{pmatrix}$.

As one vector is not a scalar multiple of the other, the lines are not parallel.

Now $t = 1 + 3s \dots (1)$ $2 - t = -2 - 2s$ $-2 + t = 2s + \frac{1}{2}$
 $-t + 2s = -4 \dots (2)$ $t - 2s = 2\frac{1}{2} \dots (3)$

Solving (1) and (2) simultaneously: $-(1 + 3s) + 2s = -4$
 $\therefore -1 - 3s + 2s = -4$
 $\therefore -s = -3$
 $\therefore s = 3$ and so $t = 1 + 3(3) = 10$

Substituting in (3), $t - 2s = 10 - 2(3) = 4 \neq 2\frac{1}{2}$

Since the system is inconsistent, the lines do not meet. $\therefore$ they are skew.

The acute angle between the lines has
$$\cos \theta = \frac{|3 + 2 + 2|}{\sqrt{1 + 1 + 1} \sqrt{9 + 4 + 4}} = \frac{7}{\sqrt{3} \sqrt{17}}$$

 $\therefore \theta \approx 11.4^\circ$

- e** Line 1 has direction vector $\begin{pmatrix} 1 \\ -1 \\ 2 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 3 \\ -2 \\ 1 \end{pmatrix}$.

As one vector is not a scalar multiple of the other, the lines are not parallel.

$$\begin{array}{lll} 1 + \lambda = 2 + 3\mu & 2 - \lambda = 3 - 2\mu & 3 + 2\lambda = \mu - 5 \\ \lambda - 3\mu = 1 \quad \dots (1) & -\lambda + 2\mu = 1 \quad \dots (2) & 2\lambda - \mu = -8 \quad \dots (3) \end{array}$$

Solving (1) and (2) simultaneously: $\lambda - 3\mu = 1$

$$-\lambda + 2\mu = 1$$

$$\text{Adding, } -\mu = 2$$

$$\therefore \mu = -2 \text{ and } \lambda - 3(-2) = 1 \therefore \lambda = -5$$

Checking in (3), $2\lambda - \mu = 2(-5) - (-2) = -10 + 2 = -8 \checkmark$

Since $\mu = -2$, $\lambda = -5$ satisfies all three equations, the lines meet.

They meet at $x = 1 + (-5)$, $y = 2 - (-5)$, $z = 3 + 2(-5)$, or at $(-4, 7, -7)$.

The acute angle between the lines has $\cos \theta = \frac{|3 + 2 + 2|}{\sqrt{1+1+4}\sqrt{9+4+1}} = \frac{7}{\sqrt{84}}$

and so $\theta \approx 40.2^\circ$

- f** Line 1 has direction vector $\begin{pmatrix} -2 \\ 1 \\ 0 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 4 \\ -2 \\ 0 \end{pmatrix}$.

Now $\begin{pmatrix} 4 \\ -2 \\ 0 \end{pmatrix} = -2 \begin{pmatrix} -2 \\ 1 \\ 0 \end{pmatrix}$, so the lines are parallel and hence $\theta = 0^\circ$.

All points on line 1 have z -coordinate 5 and all points on line 2 have z -coordinate 3.

$\therefore$ the lines are not coincident.

- g** Line 1 has direction vector $\begin{pmatrix} 2 \\ -1 \\ 3 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} -4 \\ 2 \\ -6 \end{pmatrix}$.

As $\begin{pmatrix} -4 \\ 2 \\ -6 \end{pmatrix} = -2 \begin{pmatrix} 2 \\ -1 \\ 3 \end{pmatrix}$, the two lines are parallel. Hence $\theta = 0^\circ$.

The point on line 1 where $\lambda = 1$ is $(3, -1, 4)$.

The unique point on line 2 with x -coordinate 3 is the point where $3 - 4\mu = 3 \therefore \mu = 0$.

This point is $(3, -1, 4)$.

Lines 1 and 2 are parallel and share the point $(3, -1, 4)$. $\therefore$ they are coincident and $\theta = 0^\circ$.

- 2** Line 1 is $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 3 \\ -1 \\ 2 \end{pmatrix} + \lambda \begin{pmatrix} 1 \\ -2 \\ -1 \end{pmatrix}$ with direction vector $\mathbf{a} = \begin{pmatrix} 1 \\ -2 \\ -1 \end{pmatrix}$.
- Line 2 is $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} + \mu \begin{pmatrix} -2 \\ 4 \\ 2 \end{pmatrix}$ with direction vector $\mathbf{b} = \begin{pmatrix} -2 \\ 4 \\ 2 \end{pmatrix}$.
- Line 3 is $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} + t \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}$ with direction vector $\mathbf{c} = \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}$.

Line 1 and line 2:

Since $\begin{pmatrix} -2 \\ 4 \\ 2 \end{pmatrix} = -2 \begin{pmatrix} 1 \\ -2 \\ -1 \end{pmatrix}$, line 1 and line 2 are parallel.

When $\lambda = 0$, the point on line 1 is $(3, -1, 2)$.

For line 2, $y = 4\mu$, so the unique point on line 2 with y -coordinate -1 is the point where $\mu = -\frac{1}{4}$.

This point is $(\frac{3}{2}, -1, -\frac{3}{2})$.

Since $(\frac{3}{2}, -1, -\frac{3}{2}) \neq (3, -1, 2)$, line 1 and line 2 are not coincident.

Line 1 and line 3:

Equating x , y , and z values in lines 1 and 3 gives

$$\begin{array}{lll} 3 + \lambda = t & -1 - 2\lambda = 1 + 2t & 2 - \lambda = 1 + t \\ \therefore t = 3 + \lambda & \therefore 2t = -2 - 2\lambda & \therefore \lambda + t = 1 \dots (1) \\ & \therefore t = -1 - \lambda & \end{array}$$

Solving these we get $3 + \lambda = -1 - \lambda$

$$\therefore 2\lambda = -4$$

$$\therefore \lambda = -2 \text{ and so } t = 3 - 2 \therefore t = 1$$

Checking in (1): $\lambda + t = -2 + 1 = -1 \neq 1$

So, there is no simultaneous solution to all 3 equations.

$\therefore$ the lines do not intersect.

$$\begin{pmatrix} 1 \\ -2 \\ -1 \end{pmatrix} \neq k \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix} \text{ for any } k \in \mathbb{R}.$$

$\therefore$ lines 1 and 3 are not parallel.

Since they do not intersect and are not parallel, they are skew.

$$\begin{aligned} \text{If } \theta \text{ is the acute angle between } \mathbf{a} \text{ and } \mathbf{c}, \text{ then } \cos \theta &= \frac{|\mathbf{a} \cdot \mathbf{c}|}{|\mathbf{a}| |\mathbf{c}|} = \frac{|1 - 4 - 1|}{\sqrt{1 + 4 + 1} \sqrt{1 + 4 + 1}} = \frac{4}{\sqrt{6}\sqrt{6}} = \frac{2}{3} \\ \therefore \theta &\approx 48.2^\circ \end{aligned}$$

So, line 1 and line 3 are skew with an angle of about 48.2° between them.

Line 2 and line 3:

Equating x , y , and z values in lines 2 and 3 gives

$$\begin{array}{lll} 1 - 2\mu = t & 4\mu = 1 + 2t & -1 + 2\mu = 1 + t \\ \therefore t = 1 - 2\mu & \therefore 2t = -1 + 4\mu & \therefore 2\mu - t = 2 \dots (2) \\ \therefore 2t = 2 - 4\mu & & \end{array}$$

Solving these we get $2 - 4\mu = -1 + 4\mu$

$$\therefore 8\mu = 3$$

$$\therefore \mu = \frac{3}{8} \text{ and so } t = 1 - 2(\frac{3}{8}) \therefore t = \frac{1}{4}$$

Checking in (2): $2\mu - t = 2(\frac{3}{8}) - \frac{1}{4} = \frac{6}{8} - \frac{2}{8} = \frac{4}{8} = \frac{1}{2} \neq 2$

So, there is no simultaneous solution to all 3 equations.

$\therefore$ the lines do not intersect.

$$\begin{pmatrix} -2 \\ 4 \\ 2 \end{pmatrix} \neq k \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix} \text{ for any } k \in \mathbb{R}.$$

$\therefore$ lines 2 and 3 are not parallel.

Since they do not intersect and are not parallel, they are skew.

If ϕ is the acute angle between $\mathbf{b}$ and $\mathbf{c}$ then

$$\begin{aligned} \cos \phi &= \frac{|\mathbf{b} \cdot \mathbf{c}|}{|\mathbf{b}| |\mathbf{c}|} = \frac{|-2 + 8 + 2|}{\sqrt{4 + 16 + 4} \sqrt{1 + 4 + 1}} = \frac{8}{\sqrt{144}} = \frac{2}{3} \\ \therefore \phi &\approx 48.2^\circ \end{aligned}$$

So, line 2 and line 3 are skew with an angle of about 48.2° between them.

EXERCISE 15I

1 $\mathbf{a} \quad \mathbf{n} = \begin{pmatrix} 2 \\ -1 \\ 3 \end{pmatrix}$, and the point $(-1, 2, 4)$ lies on the plane.

$$\therefore \text{ the equation is } 2x - y + 3z = 2(-1) - 2 + 3(4) \text{ which is } 2x - y + 3z = 8.$$

b $\vec{AB} = \begin{pmatrix} 3 \\ 4 \\ 1 \end{pmatrix}$ is a vector normal to the plane, and $(2, 3, 1)$ lies on the plane.

$$\therefore \text{ the equation is } 3x + 4y + z = 3(2) + 4(3) + 1$$

$$\therefore 3x + 4y + z = 19$$

c The line $x = 1 + t$, $y = 2 - t$, $z = 3 + 2t$ has direction vector $\begin{pmatrix} 1 \\ -1 \\ 2 \end{pmatrix}$.

Also, letting $t = 0$, the point $(1, 2, 3)$ lies on the plane and we call this point B.

$$\therefore \vec{AB} = \begin{pmatrix} -2 \\ 0 \\ 2 \end{pmatrix} \text{ and so a vector normal to the plane is } \vec{AB} \times \begin{pmatrix} 1 \\ -1 \\ 2 \end{pmatrix}$$

$$\therefore \mathbf{n} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2 & 0 & 2 \\ 1 & -1 & 2 \end{vmatrix} = \begin{vmatrix} 0 & 2 \\ -1 & 2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} -2 & 2 \\ 1 & 2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} -2 & 0 \\ 1 & -1 \end{vmatrix} \mathbf{k}$$

$$= 2\mathbf{i} + 6\mathbf{j} + 2\mathbf{k} \text{ or } 2(\mathbf{i} + 3\mathbf{j} + \mathbf{k})$$

$$\therefore \text{ since } A(3, 2, 1) \text{ lies on the plane, it has equation } x + 3y + z = 3 + 3(2) + 1$$

$$\text{or } x + 3y + z = 10$$

2 a $2x + 3y - z = 8$ has $\mathbf{n} = \begin{pmatrix} 2 \\ 3 \\ -1 \end{pmatrix}$ **b** $3x - y + 0z = 11$ has $\mathbf{n} = \begin{pmatrix} 3 \\ -1 \\ 0 \end{pmatrix}$

c $0x + 0y + z = 2$ has $\mathbf{n} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$ **d** $1x + 0y + 0z = 0$ has $\mathbf{n} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$

3 a The y -axis is perpendicular to the XOZ plane $\therefore$ a normal vector is $\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$

$$\therefore \text{ since the origin lies on the plane, it has equation } y = 0.$$

b Since the plane is perpendicular to the Z -axis, it has normal vector $\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$

$$\therefore \text{ since } (2, -1, 4) \text{ lies on the plane, it has equation } z = 4.$$

4 a i $\vec{AB} = \begin{pmatrix} 1 \\ 1 \\ -4 \end{pmatrix}$, $\vec{AC} = \begin{pmatrix} -1 \\ 0 \\ -2 \end{pmatrix}$, so $\mathbf{r} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 2 \\ 6 \end{pmatrix} + \lambda \begin{pmatrix} 1 \\ 1 \\ -4 \end{pmatrix} + \mu \begin{pmatrix} -1 \\ 0 \\ -2 \end{pmatrix}$

ii If $\mathbf{n}$ is the normal vector, then

$$\therefore \text{ since } A(0, 2, 6) \text{ lies on the plane, it has equation } -2x + 6y + z = -2(0) + 6(2) + 6$$

$$\therefore -2x + 6y + z = 18$$

b i $\vec{AB} = \begin{pmatrix} -3 \\ 3 \\ -2 \end{pmatrix}$, $\vec{AC} = \begin{pmatrix} -3 \\ -1 \\ -1 \end{pmatrix}$, so $\mathbf{r} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 3 \\ 1 \\ 2 \end{pmatrix} + \lambda \begin{pmatrix} -3 \\ 3 \\ -2 \end{pmatrix} + \mu \begin{pmatrix} -3 \\ -1 \\ -1 \end{pmatrix}$

$$= -5\mathbf{i} + 3\mathbf{j} + 12\mathbf{k}$$

$$\therefore \text{ since } C(0, 0, 1) \text{ lies on the plane, it has equation } -5x + 3y + 12z = 12.$$

$$\text{c} \quad \text{i} \quad \overrightarrow{AB} = \begin{pmatrix} -2 \\ -1 \\ -1 \end{pmatrix}, \quad \overrightarrow{AC} = \begin{pmatrix} 2 \\ -3 \\ -3 \end{pmatrix}, \quad \text{so} \quad \mathbf{r} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 2 \\ 0 \\ 3 \end{pmatrix} + \lambda \begin{pmatrix} -2 \\ -1 \\ -1 \end{pmatrix} + \mu \begin{pmatrix} 2 \\ -3 \\ -3 \end{pmatrix}$$

ii If $\mathbf{n}$ is the normal vector, then

$$\mathbf{n} = \overrightarrow{AB} \times \overrightarrow{AC} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2 & -1 & -1 \\ 2 & -3 & -3 \end{vmatrix} = \begin{vmatrix} -1 & -1 \\ -3 & -3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} -2 & -1 \\ 2 & -3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} -2 & -1 \\ 2 & -3 \end{vmatrix} \mathbf{k}$$

$$= -8\mathbf{j} + 8\mathbf{k} \quad \text{or} \quad -8(\mathbf{j} - \mathbf{k})$$

$\therefore$ since $A(2, 0, 3)$ lies on the plane, it has equation $y - z = -3$.

5 a The normal to $x - 3y + 4z = 8$ is $\begin{pmatrix} 1 \\ -3 \\ 4 \end{pmatrix}$, and this is the direction vector of the line.

$\therefore$ since the line passes through $(1, -2, 0)$, it has equation

$$x = 1 + \lambda, \quad y = -2 - 3\lambda, \quad z = 4\lambda, \quad \lambda \in \mathbb{R}.$$

b The normal to $x - y - 2z = 11$ is $\begin{pmatrix} 1 \\ -1 \\ -2 \end{pmatrix}$.

$\therefore$ since the line passes through $(3, 4, -1)$, it has equation

$$x = 3 + \lambda, \quad y = 4 - \lambda, \quad z = -1 - 2\lambda, \quad \lambda \in \mathbb{R}.$$

6 The line has direction vector $\overrightarrow{AB} = \begin{pmatrix} -1 \\ 3 \\ -3 \end{pmatrix}$.

$\therefore$ since the line passes through $A(2, -1, 3)$, it has parametric equations

$$x = 2 - t, \quad y = -1 + 3t, \quad z = 3 - 3t, \quad t \in \mathbb{R}.$$

This line meets $x + 2y - z = 5$ when $(2 - t) + 2(-1 + 3t) - (3 - 3t) = 5$

$$\therefore 2 - t - 2 + 6t - 3 + 3t = 5$$

$\therefore 8t = 8 \quad \therefore t = 1$, and so they meet at $(1, 2, 0)$.

7 a The direction vector of the line is $\overrightarrow{PQ} = \begin{pmatrix} 1 \\ 2 \\ -5 \end{pmatrix}$.

$\therefore$ since it passes through $P(1, -2, 4)$, it has parametric equations

$$x = 1 + t, \quad y = -2 + 2t, \quad z = 4 - 5t, \quad t \in \mathbb{R}.$$

b i The line meets the YOZ plane when $x = 0$, or when $t = -1$.
This corresponds to the point $(0, -4, 9)$.

ii The line meets $y + z = 2$ when $-2 + 2t + 4 - 5t = 2 \quad \therefore -3t = 0 \quad \therefore t = 0$
This corresponds to the point $(1, -2, 4)$.

iii The line meets $\frac{x-3}{2} = \frac{y+2}{3} = \frac{z-30}{-1}$

$$\text{when} \quad \frac{1+t-3}{2} = \frac{-2+2t+2}{3} = \frac{4-5t-30}{-1}$$

$$\therefore \frac{t-2}{2} = \frac{2t}{3} = 5t+26$$

$$\therefore 3t-6 = 4t = 30t+156$$

$$\therefore 3t-6 = 4t \quad \text{and} \quad 4t = 30t+156$$

$$\therefore t = -6 \quad \text{and} \quad -26t = 156$$

$$\therefore t = -6 \quad \text{is a common solution}$$

$\therefore$ the lines meet at the point corresponding to $t = -6$, which is $(-5, -14, 34)$.

8 a The plane $2x + y - 2z = -11$ has $\mathbf{n} = \begin{pmatrix} 2 \\ 1 \\ -2 \end{pmatrix}$.

$\therefore$ the parametric equations of (AN) are $x = 1 + 2t$, $y = 0 + t$, $z = 2 - 2t$, $t \in \mathbb{R}$.

This line meets the plane when $2(1 + 2t) + t - 2(2 - 2t) = -11$

$$\therefore 2 + 4t + t - 4 + 4t = -11$$

$$\therefore 9t = -9$$

$$\therefore t = -1$$

Thus N is $(-1, -1, 4)$ and $\therefore \overrightarrow{AN} = \begin{pmatrix} -2 \\ -1 \\ 2 \end{pmatrix}$ and $AN = \sqrt{(-2)^2 + (-1)^2 + 2^2}$
 $= \sqrt{9} = 3$ units

b The plane $x - y + 3z = -10$ has $\mathbf{n} = \begin{pmatrix} 1 \\ -1 \\ 3 \end{pmatrix}$

$\therefore$ the parametric equations of (AN) are $x = 2 + t$, $y = -1 - t$, $z = 3 + 3t$, $t \in \mathbb{R}$.

This line meets the plane when $(2 + t) - (-1 - t) + 3(3 + 3t) = -10$

$$\therefore 2 + t + 1 + t + 9 + 9t = -10$$

$$\therefore 11t = -22$$

$$\therefore t = -2$$

$\therefore$ N is $(0, 1, -3)$

$\therefore \overrightarrow{AN} = \begin{pmatrix} -2 \\ 2 \\ -6 \end{pmatrix}$ and $AN = \sqrt{(-2)^2 + 2^2 + (-6)^2} = \sqrt{44} = 2\sqrt{11}$ units.

c The plane $4x - y - 2z = 8$ has $\mathbf{n} = \begin{pmatrix} 4 \\ -1 \\ -2 \end{pmatrix}$.

$\therefore$ the parametric equations of (AN) are

$$x = 1 + 4t, \quad y = -4 - t, \quad z = -3 - 2t, \quad t \in \mathbb{R}.$$

This line meets the plane when $4(1 + 4t) - (-4 - t) - 2(-3 - 2t) = 8$

$$\therefore 4 + 16t + 4 + t + 6 + 4t = 8$$

$$\therefore 21t = -6$$

$$\therefore t = -\frac{2}{7}$$

$\therefore$ N is $(-\frac{1}{7}, -\frac{26}{7}, -\frac{17}{7})$, $\therefore \overrightarrow{AN} = \begin{pmatrix} -\frac{8}{7} \\ \frac{2}{7} \\ \frac{4}{7} \end{pmatrix}$ and so $AN = \sqrt{(-\frac{8}{7})^2 + (\frac{2}{7})^2 + (\frac{4}{7})^2}$
 $= \sqrt{\frac{84}{49}} = 2\sqrt{\frac{3}{7}}$ units

9 The mirror image lies on the normal line to the plane through the object point.

Now $x + 2y + z = 1$ has $\mathbf{n} = \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}$

$\therefore$ the normal at A has parametric equations $x = 3 + t$, $y = 1 + 2t$, $z = 2 + t$, $t \in \mathbb{R}$.

This line meets the plane when $(3 + t) + 2(1 + 2t) + 2 + t = 1$

$$\therefore 3 + t + 2 + 4t + 2 + t = 1$$

$$\therefore 6t = -6$$

$$\therefore t = -1$$

$\therefore$ N is $(2, -1, 1)$

If A' is the mirror image of A, then $\overrightarrow{AN} = \overrightarrow{NA'}$

$\therefore$ letting A' have coordinates (a, b, c) , $\begin{pmatrix} -1 \\ -2 \\ -1 \end{pmatrix} = \begin{pmatrix} a - 2 \\ b + 1 \\ c - 1 \end{pmatrix}$

$\therefore a - 2 = -1$, $b + 1 = -2$, $c - 1 = -1$ and so A' is at $(1, -3, 0)$.

10 The plane $x + 4y - z = -2$ has normal $\mathbf{n} = \begin{pmatrix} 1 \\ 4 \\ -1 \end{pmatrix}$ which passes through $(3, 4, -1)$.

$\therefore$ the normal has parametric equations $x = 3 + t$, $y = 4 + 4t$, $z = -1 - t$, $t \in \mathbb{R}$ and will meet any of the coordinate axes if any two of the values of x , y , and z are zero at the same time.

$\therefore$ since $x = 0$ when $t = -3$ and $y = z = 0$ when $t = -1$, the normal meets the X -axis when $t = -1$, at the point $(2, 0, 0)$.

11 $\overrightarrow{AB} = \begin{pmatrix} -1 \\ -3 \\ -1 \end{pmatrix}$

a The normal $\mathbf{n}$ is perpendicular to both the X -axis and $\overrightarrow{AB}$.

Since the X -axis has direction vector $\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$,

$$\begin{aligned} \mathbf{n} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 0 \\ -1 & -3 & -1 \end{vmatrix} \\ &= \begin{vmatrix} 0 & 0 \\ -3 & -1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 0 \\ -1 & -1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 0 \\ -1 & -3 \end{vmatrix} \mathbf{k} \\ &= \mathbf{j} - 3\mathbf{k} \end{aligned}$$

Since $A(1, 2, 3)$ is in the plane, the plane has equation $y - 3z = 1(2) - 3(3)$
or $y - 3z = -7$

b The normal $\mathbf{n}$ is perpendicular to both the Y -axis and $\overrightarrow{AB}$.

Since the Y -axis has direction vector $\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$,

$$\begin{aligned} \mathbf{n} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 1 & 0 \\ -1 & -3 & -1 \end{vmatrix} \\ &= \begin{vmatrix} 1 & 0 \\ -3 & -1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & 0 \\ -1 & -1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & 1 \\ -1 & -3 \end{vmatrix} \mathbf{k} \\ &= -\mathbf{i} + \mathbf{k} \end{aligned}$$

Since $A(1, 2, 3)$ is in the plane, the plane has equation $-x + z = -1(1) + 1(3) = 2$
 $\therefore x - z = -2$

c The normal $\mathbf{n}$ is perpendicular to both the Z -axis and $\overrightarrow{AB}$.

Since the Z -axis has direction vector $\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$,

$$\begin{aligned} \mathbf{n} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 0 & 1 \\ -1 & -3 & -1 \end{vmatrix} \\ &= \begin{vmatrix} 0 & 1 \\ -3 & -1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 0 & 1 \\ -1 & -1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 0 & 0 \\ -1 & -3 \end{vmatrix} \mathbf{k} \\ &= 3\mathbf{i} - \mathbf{j} \end{aligned}$$

Since $A(1, 2, 3)$ is in the plane, the plane has equation $3x - y = 3(1) - 1(2)$
or $3x - y = 1$

12 Now $x - 1 = \frac{y - 2}{2} = z + 3$ has direction vector $\begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix}$

and $x + 1 = y - 3 = 2z + 5$ has direction vector $\begin{pmatrix} 1 \\ 1 \\ \frac{1}{2} \end{pmatrix}$ $\left\{ \text{since } 2z + 5 = \frac{z + \frac{5}{2}}{\frac{1}{2}} \right\}$

$\therefore$ a vector perpendicular to both lines is:

$$\begin{aligned} \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix} \times \begin{pmatrix} 1 \\ 1 \\ \frac{1}{2} \end{pmatrix} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 1 \\ 1 & 1 & \frac{1}{2} \end{vmatrix} = \begin{vmatrix} 2 & 1 \\ 1 & \frac{1}{2} \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & 1 \\ 1 & \frac{1}{2} \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 2 \\ 1 & 1 \end{vmatrix} \mathbf{k} \\ &= 0\mathbf{i} + \frac{1}{2}\mathbf{j} - \mathbf{k} \end{aligned}$$

$\therefore \begin{pmatrix} 0 \\ 1 \\ -2 \end{pmatrix}$ is perpendicular to both lines.

A plane with normal $\begin{pmatrix} 0 \\ 1 \\ -2 \end{pmatrix}$ has equation $y - 2z = c$ for some c .

Now for line 1, $\frac{y-2}{2} = z+3$ and for line 2, $y-3 = 2z+5$
 $\therefore y-2 = 2z+6$ $\therefore y-2z = 8$ also.
 $\therefore y-2z = 8$

$\therefore y - 2z = 8$ is a plane containing both lines, so the lines are coplanar.

- 13 a** Since $A(1, 2, k)$ lies on $x + 2y - 2z = 8$, $1 + 2(2) - 2k = 8$
 $\therefore 1 + 4 - 2k = 8$
 $\therefore -2k = 3$
 $\therefore k = -\frac{3}{2}$

- b** Since $x + 2y - 2z = 8$, the plane has normal vector $\mathbf{n} = \begin{pmatrix} 1 \\ 2 \\ -2 \end{pmatrix}$.

$\therefore$ the normal from A has parametric equations

$$x = 1 + t, \quad y = 2 + 2t, \quad z = -\frac{3}{2} - 2t, \quad t \in \mathbb{R}.$$

$\therefore$ points of the normal that are 6 units from A have

$$\begin{aligned} \sqrt{(1+t-1)^2 + (2+2t-2)^2 + (-\frac{3}{2}-2t+\frac{3}{2})^2} &= 6 \\ \therefore \sqrt{t^2 + 4t^2 + 4t^2} &= 6 \\ \therefore 9t^2 &= 36 \\ \therefore t^2 &= 4 \\ \therefore t &= \pm 2 \end{aligned}$$

$\therefore$ B is $(3, 6, -\frac{11}{2})$ or $(-1, -2, \frac{5}{2})$

- 14 a** The normal from $A(3, 2, 1)$ to the plane has direction vector

$$\begin{aligned} \mathbf{n} = (2\mathbf{i} + \mathbf{j} + \mathbf{k}) \times (4\mathbf{i} + 2\mathbf{j} - 2\mathbf{k}) &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 1 & 1 \\ 4 & 2 & -2 \end{vmatrix} \\ &= \begin{vmatrix} 1 & 1 \\ 2 & -2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 2 & 1 \\ 4 & -2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 2 & 1 \\ 4 & 2 \end{vmatrix} \mathbf{k} \\ &= -4\mathbf{i} + 8\mathbf{j} \\ \therefore \text{if N is the foot of the normal from A, (AN)} & \\ \text{has equation } \begin{pmatrix} x \\ y \\ z \end{pmatrix} &= \begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix} + t \begin{pmatrix} -4 \\ 8 \\ 0 \end{pmatrix} \end{aligned}$$

So, N has coordinates of the form $(3 - 4t, 2 + 8t, 1)$

$$\text{But N lies on the plane } \therefore \begin{pmatrix} 3-4t \\ 2+8t \\ 1 \end{pmatrix} = \begin{pmatrix} 3 \\ 1 \\ 2 \end{pmatrix} + \lambda \begin{pmatrix} 2 \\ 1 \\ 1 \end{pmatrix} + \mu \begin{pmatrix} 4 \\ 2 \\ -2 \end{pmatrix}$$

$$\therefore \begin{cases} 3-4t = 3+2\lambda+4\mu \\ 2+8t = 1+\lambda+2\mu \\ 1 = 2+\lambda-2\mu \end{cases} \text{ and so } \begin{cases} 2\lambda+4\mu+4t = 0 \\ \lambda+2\mu-8t = 1 \\ \lambda-2\mu = -1 \end{cases}$$

Solving simultaneously using technology gives $\lambda = -0.4, \mu = 0.3, t = -0.1$

$\therefore$ N is $(3 - 4(-0.1), 2 + 8(-0.1), 1)$ or $(3.4, 1.2, 1)$

$$\therefore \overrightarrow{AN} = \begin{pmatrix} 3.4-3 \\ 1.2-2 \\ 1-1 \end{pmatrix} = \begin{pmatrix} 0.4 \\ -0.8 \\ 0 \end{pmatrix} \text{ and } |\overrightarrow{AN}| = \sqrt{(0.4)^2 + (0.8)^2 + 0^2} = \frac{2}{\sqrt{5}} \text{ units}$$

- 15 b** and **c** are non-parallel vectors in the plane. The normal vector to the plane is $\mathbf{n} = \mathbf{b} \times \mathbf{c}$.

$$d = \frac{|2x_1 + 2y_1 + 4z_1 + 11|}{\sqrt{2^2 + 2^2 + 4^2}} = \frac{|2(0) + 2(0) + 4(2) + 11|}{\sqrt{24}} = \frac{19}{\sqrt{24}} \text{ units.}$$

- b** Choose a point on the plane $ax + by + cz + d_1 = 0$, for example, $\left(0, 0, -\frac{d_1}{c}\right)$.

Using the formula obtained in **16 b** to calculate the distance from this point to the second plane,

$$d = \frac{|ax_1 + by_1 + cz_1 + d_2|}{\sqrt{a^2 + b^2 + c^2}} = \frac{\left|a(0) + b(0) + c\left(-\frac{d_1}{c}\right) + d_2\right|}{\sqrt{a^2 + b^2 + c^2}} = \frac{|d_2 - d_1|}{\sqrt{a^2 + b^2 + c^2}} \text{ units}$$

- 18** The line $x = 2 + t$, $y = -1 + 2t$, $z = -3t$ has direction vector $\begin{pmatrix} 1 \\ 2 \\ -3 \end{pmatrix}$,

and $\begin{pmatrix} 11 \\ -4 \\ 1 \end{pmatrix}$ is a vector normal to the plane $11x - 4y + z = 0$.

But $\begin{pmatrix} 1 \\ 2 \\ -3 \end{pmatrix} \bullet \begin{pmatrix} 11 \\ -4 \\ 1 \end{pmatrix} = 11 - 8 - 3 = 0$

$\therefore$ these vectors are perpendicular and so the line is parallel to the plane.

Choose any point on the line, say $t = 0$, which corresponds to the point $(2, -1, 0)$.

Then the distance $d = \frac{|11x_1 - 4y_1 + z_1|}{\sqrt{11^2 + (-4)^2 + 1^2}} = \frac{|11(2) - 4(-1) + 0|}{\sqrt{138}} = \frac{26}{\sqrt{138}}$ units

- 19** Since the planes are parallel to $2x - y + 2z = 5$, they have equation $2x - y + 2z = a$ for some a .
Choose any point on $2x - y + 2z = 5$, for example, $(0, -5, 0)$.

Then the distance from this point to the plane $2x - y + 2z = a$ is

$$d = \frac{|2x_1 - y_1 + 2z_1 - a|}{\sqrt{2^2 + (-1)^2 + 2^2}} \quad \therefore 5 - a = \pm 6$$

$$\therefore a = 5 \pm 6$$

$$\therefore a = -1 \text{ or } a = 11$$

$$\therefore 2 = \frac{|2(0) - (-5) + 2(0) - a|}{3} \quad \therefore \text{the planes are } 2x - y + 2z = -1$$

$$\therefore 6 = |5 - a| \quad \text{and } 2x - y + 2z = 11$$

and so $\phi \approx 0^\circ$

So, the line and plane are parallel.

So, if $x - 4 = 3 - y = 2(z + 1) = t$

EXERCISE 15K

- 1 a In augmented matrix form, the system is:

$$\left[\begin{array}{ccc|c} 1 & -2 & 5 & 1 \\ 2 & -4 & 8 & 2 \\ -3 & 6 & 7 & -3 \end{array} \right] \quad \begin{array}{ccc|c} 2 & -4 & 8 & 2 \\ -2 & 4 & -10 & -2 \\ \hline 0 & 0 & -2 & 0 \\ -3 & 6 & 7 & -3 \\ 3 & -6 & 15 & 3 \\ \hline 0 & 0 & 22 & 0 \end{array}$$

$$\sim \left[\begin{array}{ccc|c} 1 & -2 & 5 & 1 \\ 0 & 0 & -2 & 0 \\ 0 & 0 & 22 & 0 \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - 2R_1 \\ R_3 \rightarrow R_3 + 3R_1 \end{array}$$

Rows 2 and 3 show $-2z = 0$ and $22z = 0$, so $z = 0$.

Row 1 becomes $x - 2y + 5(0) = 1$

let $y = t$, then $x - 2t = 1$

$$\therefore x = 1 + 2t$$

$\therefore$ there are infinitely many solutions of the form $x = 1 + 2t$, $y = t$, $z = 0$, $t \in \mathbb{R}$.

- b In augmented matrix form, the system is:

$$\left[\begin{array}{ccc|c} 1 & 4 & 11 & 7 \\ 1 & 6 & 17 & 9 \\ 1 & 4 & 8 & 4 \end{array} \right] \quad \begin{array}{ccc|c} 1 & 6 & 17 & 9 \\ -1 & -4 & -11 & -7 \\ \hline 0 & 2 & 6 & 2 \\ 1 & 4 & 8 & 4 \\ -1 & -4 & -11 & -7 \\ \hline 0 & 0 & -3 & -3 \end{array}$$

$$\sim \left[\begin{array}{ccc|c} 1 & 4 & 11 & 7 \\ 0 & 2 & 6 & 2 \\ 0 & 0 & -3 & -3 \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - R_1 \\ R_3 \rightarrow R_3 - R_1 \end{array}$$

The last row gives $-3z = -3 \quad \therefore z = 1$

$\therefore$ in row 2, $2y + 6z = 2$

$$\therefore 2y + 6 = 2$$

$$\therefore y = -2$$

and in row 1, $x + 4y + 11z = 7$

$$\therefore x + 4(-2) + 11(1) = 7$$

$$\therefore x + 3 = 7$$

$$\therefore x = 4$$

Thus we have a unique solution $x = 4$, $y = -2$, $z = 1$.

c In augmented matrix form, the system is:

$$\begin{aligned}
 & \left[\begin{array}{ccc|c} 2 & -1 & 3 & 17 \\ 2 & -2 & -5 & 4 \\ 3 & 2 & 2 & 10 \end{array} \right] \sim \left[\begin{array}{ccc|c} 2 & -1 & 3 & 17 \\ 0 & -1 & -8 & -13 \\ 0 & 7 & -5 & -31 \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - R_1 \\ R_3 \rightarrow 2R_3 - 3R_1 \end{array} \\
 & \sim \left[\begin{array}{ccc|c} 2 & -1 & 3 & 17 \\ 0 & -1 & -8 & -13 \\ 0 & 0 & -61 & -122 \end{array} \right] \begin{array}{l} \\ \\ R_3 \rightarrow R_3 + 7R_2 \end{array} \\
 & \begin{array}{cccc} 2 & -2 & -5 & 4 \\ -2 & 1 & -3 & -17 \\ \hline 0 & -1 & -8 & -13 \\ 6 & 4 & 4 & 20 \\ -6 & 3 & -9 & -51 \\ \hline 0 & 7 & -5 & -31 \\ 0 & 7 & -5 & -31 \\ 0 & -7 & -56 & -91 \\ \hline 0 & 0 & -61 & -122 \end{array}
 \end{aligned}$$

The last row gives $-61z = -122 \quad \therefore z = 2$

$$\begin{aligned}
 \therefore \text{ in row 2, } -y - 8z &= -13 & \text{and in row 1, } 2x - y + 3z &= 17 \\
 \therefore -y - 16 &= -13 & \therefore 2x + 3 + 6 &= 17 \\
 \therefore y &= -3 & \therefore 2x &= 8 \\
 & & \therefore x &= 4
 \end{aligned}$$

Thus we have a unique solution $x = 4, y = -3, z = 2$.

d In augmented matrix form, the system is:

$$\begin{aligned}

 & \sim \left[\begin{array}{ccc|c} 2 & 3 & 4 & 1 \\ 0 & -3 & -6 & -1 \\ 0 & 0 & 0 & 1 \end{array} \right] \begin{array}{l} \\ \\ R_3 \rightarrow R_3 - R_2 \end{array} \\
 & \begin{array}{cccc} 10 & 12 & 14 & 4 \\ -10 & -15 & -20 & -5 \\ \hline 0 & -3 & -6 & -1 \\ 8 & 9 & 10 & 4 \\ -8 & -12 & -16 & -4 \\ \hline 0 & -3 & -6 & 0 \end{array}
 \end{aligned}$$

In row 3, $0z = 1$

$\therefore$ the system is inconsistent and has no real solutions.

 $\therefore -4z = -20$ and $x - 3y + 2z = 8$ or $x = 3y - 2z + 8$
 $\therefore z = 5$ and if we let $y = t$, then $x = 3t - 2(5) + 8 = -2 + 3t$
 $\therefore$ the planes meet in the line $x = -2 + 3t, y = t, z = 5, t \in \mathbb{R}$

ii $\left[\begin{array}{ccc|c} 2 & 1 & 1 & 5 \\ 1 & -1 & 1 & 3 \end{array} \right] \sim \left[\begin{array}{ccc|c} 2 & 1 & 1 & 5 \\ 0 & -3 & 1 & 1 \end{array} \right] R_2 \rightarrow 2R_2 - R_1$
 $\therefore -3y + z = 1$ and $2x + y + z = 5$
 $\therefore$ if we let $y = t$, then $z = 1 + 3y = 1 + 3t$ and $2x = 5 - y - z$
 $= 5 - t - (1 + 3t)$
 $= 4 - 4t$
 $\therefore x = 2 - 2t$

$\therefore$ the planes meet in the line $x = 2 - 2t, y = t, z = 1 + 3t, t \in \mathbb{R}$

iii $\left[\begin{array}{ccc|c} 1 & 2 & -3 & 6 \\ 3 & 6 & -9 & 18 \end{array} \right] \sim \left[\begin{array}{ccc|c} 1 & 2 & -3 & 6 \\ 0 & 0 & 0 & 0 \end{array} \right] R_2 \rightarrow R_2 - 3R_1$
 $\therefore$ there are infinitely many solutions, as the planes are coincident.

Let $y = s$ and $z = t$ in $x + 2y - 3z = 6$, $s, t \in \mathbb{R}$

$$\therefore x = 3t - 2s + 6$$

$\therefore x = 3t - 2s + 6$, $y = s$, $z = t$, $s, t \in \mathbb{R}$ is the general solution of the plane.

$\therefore$ the planes meet at the unique point $(1, -2, 4)$

$\therefore$ the three planes meet in a common line

$$x = \frac{9-t}{3}, \quad y = \frac{5t+6}{3}, \quad z = t, \quad t \in \mathbb{R}$$

Now $-11z = -44 \therefore z = 4$

and $-2y + 3z = 16$

$$\therefore -2y + 12 = 16$$

$$\therefore -2y = 4$$

$$\therefore y = -2$$

and $x + y - z = -5$

$$\therefore x = -5 - (-2) + 4$$

$$\therefore x = 1$$

Let $z = t$

As $3y - 5z = 6$

$$3y = 5t + 6$$

$$\therefore y = \frac{5t+6}{3}$$

But $x - y + 2z = 1$

$$\therefore x = 1 + \frac{5t+6}{3} - 2t$$

$$\therefore x = \frac{3+5t+6-6t}{3}$$

$$\therefore x = \frac{9-t}{3}$$

There are two coincident planes cut by a third plane.

$\therefore$ infinitely many solutions in a line:

$$x = \frac{t+5}{2}, \quad y = \frac{3t-3}{2}, \quad z = t, \quad t \in \mathbb{R}$$

Let $z = t$

Now $-2y + 3z = 3$

$$\therefore 2y = 3z - 3$$

$$\therefore y = \frac{3t-3}{2}$$

and as $x + y - 2z = 1$

$$\therefore x = 1 - y + 2z$$

$$\therefore x = 1 - \frac{3t-3}{2} + 2t$$

$$\therefore x = \frac{2-3t+3+4t}{2}$$

$$\therefore x = \frac{t+5}{2}$$

f The system has augmented matrix:

$$\begin{aligned} & \left[\begin{array}{ccc|c} 1 & -1 & -1 & 5 \\ 1 & 1 & 1 & 1 \\ 5 & -1 & 2 & 17 \end{array} \right] \\ & \sim \left[\begin{array}{ccc|c} 1 & -1 & -1 & 5 \\ 0 & 2 & 2 & -4 \\ 0 & 4 & 7 & -8 \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - R_1 \\ R_3 \rightarrow R_3 - 5R_1 \end{array} \\ & \sim \left[\begin{array}{ccc|c} 1 & -1 & -1 & 5 \\ 0 & 2 & 2 & -4 \\ 0 & 0 & 3 & 0 \end{array} \right] R_3 \rightarrow R_3 - 2R_2 \end{aligned}$$

Now $3z = 0$

$$\therefore z = 0$$

As $2y + 2z = -4$

$$\therefore 2y = -4$$

$$\therefore y = -2$$

and as $x - y - z = 5$

$$\therefore x = 5 + (-2) + 0$$

$$\therefore x = 3$$

$\therefore$ the planes meet at the unique point $(3, -2, 0)$.

6 The system has augmented matrix:

$$\begin{aligned} & \left[\begin{array}{ccc|c} 1 & -1 & 3 & 1 \\ 2 & -3 & -1 & 3 \\ 3 & -5 & -5 & k \end{array} \right] \\ & \sim \left[\begin{array}{ccc|c} 1 & -1 & 3 & -1 \\ 0 & -1 & -7 & 1 \\ 0 & -2 & -14 & k-3 \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - 2R_1 \\ R_3 \rightarrow R_3 - 3R_1 \end{array} \\ & \sim \left[\begin{array}{ccc|c} 1 & -1 & 3 & -1 \\ 0 & -1 & -7 & 1 \\ 0 & 0 & 0 & k-5 \end{array} \right] R_3 \rightarrow R_3 - 2R_2 \end{aligned}$$

- (1) If $k = 5$, the planes meet in a line {as we have a row of zeros}

$$\text{Let } z = t$$

$$\text{Now } -y - 7z = 1$$

$$\therefore y = -1 - 7t$$

$$\text{and } x - y + 3z = 1$$

$$\therefore x = 1 + y - 3z$$

$$\therefore x = 1 - 1 - 7t - 3t$$

$$\therefore x = -10t$$

$$\therefore x = -10t, y = -1 - 7t, z = t, t \in \mathbb{R}$$

- (2) If $k \neq 5$ there are no solutions.

Since no two planes are parallel, the line of intersection of any two planes is parallel to the third plane.

- 7 a** In augmented matrix form, the system is:

$$\begin{aligned} & \left[\begin{array}{ccc|c} 1 & 3 & 3 & a-1 \\ 2 & -1 & 1 & 7 \\ 3 & -5 & a & 16 \end{array} \right] \\ & \sim \left[\begin{array}{ccc|c} 1 & 3 & 3 & a-1 \\ 0 & -7 & -5 & 9-2a \\ 0 & -14 & a-9 & 19-3a \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - 2R_1 \\ R_3 \rightarrow R_3 - 3R_1 \end{array} \\ & \sim \left[\begin{array}{ccc|c} 1 & 3 & 3 & a-1 \\ 0 & -7 & -5 & 9-2a \\ 0 & 0 & a+1 & a+1 \end{array} \right] R_3 \rightarrow R_3 - 2R_2 \\ & \begin{array}{cccc} 2 & -1 & 1 & 7 \\ -2 & -6 & -6 & -2a+2 \\ \hline 0 & -7 & -5 & 9-2a \\ 3 & -5 & a & 16 \\ -3 & -9 & -9 & -3a+3 \\ \hline 0 & -14 & a-9 & 19-3a \\ 0 & -14 & a-9 & 19-3a \\ 0 & 14 & 10 & 4a-18 \\ \hline 0 & 0 & a+1 & a+1 \end{array} \end{aligned}$$

- b** If $a = -1$, row 3 is a row of zeros, so there are infinitely many solutions, as we have 2 equations in 3 unknowns.

$$\text{Let } z = t \text{ in row 2, then } -7y - 5t = 9 - 2(-1)$$

$$\therefore -7y - 5t = 11$$

$$\therefore y = \frac{-5t - 11}{7}$$

$$\text{and substituting in row 1 gives } x + 3\left(\frac{-5t - 11}{7}\right) + 3t = (-1) - 1$$

$$\therefore x - \frac{15t}{7} - \frac{33}{7} + 3t = -2 \text{ and so, } x = \frac{19}{7} - \frac{6t}{7}$$

$$\therefore \text{there are infinitely many solutions of form } x = \frac{19 - 6t}{7}, y = \frac{-5t - 11}{7}, z = t, t \in \mathbb{R}.$$

In this case we have three planes which meet in a line.

- c** If $a \neq -1$, then $(a+1)z = a+1 \therefore z = 1$

$$\text{From row 2, } -7y - 5(1) = 9 - 2a$$

$$\therefore -7y = -2a + 14$$

$$y = \frac{2a}{7} - 2$$

$$\text{and substituting in row 1 gives } x + 3\left(\frac{2a}{7} - 2\right) + 3(1) = a - 1$$

$$\therefore x + \frac{6a}{7} - 6 + 3 = a - 1$$

$$\therefore x = \frac{a}{7} + 2$$

$$\therefore \text{the unique solution is } x = \frac{1}{7}a + 2, y = \frac{2}{7}a - 2, z = 1.$$

In this case we have three planes which meet at a point.

8 In augmented matrix form, the system is:

$$\begin{aligned}
 & \left[\begin{array}{ccc|c} 1 & 2 & m & -1 \\ m & -2 & 1 & 1 \\ 2 & 1 & -1 & 3 \end{array} \right] \sim \left[\begin{array}{ccc|c} 1 & 2 & m & -1 \\ 0 & -2(m+1) & 1-m^2 & 1+m \\ 0 & -3 & -1-2m & 5 \end{array} \right] \begin{array}{l} \\ R_2 \rightarrow R_2 - mR_1 \\ R_3 \rightarrow R_3 - 2R_1 \end{array} \\
 & \sim \left[\begin{array}{ccc|c} 1 & 2 & m & -1 \\ 0 & -2(m+1) & 1-m^2 & 1+m \\ 0 & 0 & (m+1)(m+5) & -7(m+1) \end{array} \right] \begin{array}{l} \\ \\ R_3 \rightarrow -2(m+1)R_3 + 3R_2 \end{array} \\
 & \begin{array}{ccc|c} 0 & 6(m+1) & 2(m+1)(1+2m) & -10(m+1) \\ 0 & -6(m+1) & 3(1-m^2) & 3(1+m) \\ 0 & 0 & 2(2m^2+3m+1)+3-3m^2 & -7(m+1) \end{array} \\
 & \begin{array}{l} \\ \\ = m^2 + 6m + 5 \\ = (m+1)(m+5) \end{array}
 \end{aligned}$$

a If $m = -5$, row 3 becomes $0x + 0y + 0z = 28$

$\therefore$ the system is inconsistent and there are no solutions.

In this case we have three planes with no common point of intersection. No two planes are coincident or parallel. So, the line of intersection of any two planes is parallel to the third.

b If $m = -1$, row 3 is a row of zeros, so we have 2 equations in 3 unknowns.

$\therefore$ there are infinitely many solutions.

When $m = -1$ the equations become

$$\begin{cases} x + 2y - z = -1 \\ -x - 2y + z = 1 \\ 2x + y - z = 3 \end{cases} \quad \begin{array}{l} \text{equations 1 and 2 are equivalent.} \\ \text{In this case two planes are coincident} \\ \text{and the third meets in a line.} \end{array}$$

c **i** If $m \neq -5$ or -1 , there is a unique solution. The planes meet at a point.

ii If $m \neq -1$ and $m \neq -5$, then row 3 becomes

$$(m+1)(m+5)z = -7(m+1)$$

$$\therefore z = \frac{-7}{m+5} \quad \text{and substituting in row 2 gives}$$

$$-2(m+1)y + (1-m^2)\left(\frac{-7}{m+5}\right) = 1+m$$

$$\therefore -2(m+1)(m+5)y - 7(1-m^2) = (1+m)(m+5)$$

$$\therefore -2(m+1)(m+5)y = m^2 + 6m + 5 + 7 - 7m^2$$

$$\therefore -2(m+1)(m+5)y = -6m^2 + 6m + 12$$

$$\therefore -2(m+1)(m+5)y = -6(m^2 - m - 2)$$

$$\therefore (m+1)(m+5)y = 3(m+1)(m-2)$$

$$\therefore y = \frac{3(m-2)}{m+5}$$

$$\text{and substituting in row 1 gives} \quad x + \frac{6(m-2)}{m+5} + \frac{-7m}{m+5} = -1$$

$$\therefore x(m+5) + 6(m-2) - 7m = -(m+5)$$

$$\therefore x(m+5) + 6m - 12 - 7m = -m - 5$$

$$\therefore x(m+5) = 7$$

$$\therefore x = \frac{7}{m+5}$$

$\therefore$ the system has a unique solution for all m except $m = -5$ and $m = -1$, and the

$$\text{solution is } x = \frac{7}{m+5}, \quad y = \frac{3(m-2)}{m+5}, \quad z = \frac{-7}{m+5}.$$

$$\therefore \begin{cases} 2 + 3\lambda + \mu = 3 + 2r + s \\ -1 + \mu = -1 + s \\ \lambda - \mu = 3 - r \end{cases} \quad \text{which gives} \quad \begin{cases} 3\lambda + \mu = 2r + s + 1 \\ \mu = s \\ \lambda - \mu = 3 - r \end{cases}$$

If $\mu = a$ say, then $s = a$, $3\lambda + a = 2r + a + 1$, and $\lambda - a = 3 - r$
 $\therefore r = 3 - \lambda + a$

$$\therefore 3\lambda + a = 6 - 2\lambda + 2a + a + 1$$

$$\therefore 5\lambda = 2a + 7$$

$$\therefore \lambda = \frac{2a+7}{5} \quad \text{and} \quad r = 3 + a - \frac{2a+7}{5}$$

$$\therefore r = \frac{3a+8}{5}$$

$$\therefore \begin{cases} 3 + 2r + s = 2 + t \\ -1 + s = -1 - t + u \\ 3 - r = 2 - 2u \end{cases} \quad \text{which gives} \quad \begin{cases} 2r + s + 1 = t \\ s = u - t \\ 2u - r = -1 \end{cases}$$

So, if $u = b$ say, then $r = 2b + 1$ and $4b + 2 + b - t + 1 = t$

$$\therefore 5b + 3 = 2t \quad \text{and so} \quad t = \frac{5b+3}{2}$$

$$\text{and } s = u - t = b - \frac{5b+3}{2} = \frac{-3b-3}{2}$$

$$\text{So, if } u = b, \quad r = 2b + 1, \quad t = \frac{5b+3}{2}, \quad s = \frac{-3b-3}{2} \quad \dots (2)$$

$$\text{From (1) and (2), } \frac{3a+8}{5} = 2b + 1 \quad \text{and} \quad a = \frac{-3b-3}{2}$$

$$\therefore 3a + 8 = 10b + 5 \quad \text{and} \quad 2a = -3b - 3$$

$$\therefore \begin{cases} 3a - 10b = -3 \\ 2a + 3b = -3 \end{cases} \quad \text{which has solutions} \quad a = -\frac{39}{29}, \quad b = -\frac{3}{29}$$

$$\text{In (2), } u = -\frac{3}{29}, \quad t = \frac{5(-\frac{3}{29}) + 3}{2} = 1\frac{7}{29} \quad \text{or} \quad \frac{36}{29}$$

$$\therefore \mathbf{r}_3 = \begin{pmatrix} 2 \\ -1 \\ 2 \end{pmatrix} + \frac{36}{29} \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} + \frac{3}{29} \begin{pmatrix} 0 \\ -1 \\ 2 \end{pmatrix} = \begin{pmatrix} 3\frac{7}{29} \\ -2\frac{10}{29} \\ 2\frac{6}{29} \end{pmatrix} = \begin{pmatrix} \frac{94}{29} \\ -\frac{68}{29} \\ \frac{64}{29} \end{pmatrix}$$

$\therefore$ all 3 planes meet at $(\frac{94}{29}, -\frac{68}{29}, \frac{64}{29})$.

$$\therefore t^2 = 4$$

$$\therefore t = \pm 2 \quad \therefore \text{ the points are } (-5, 2, 9) \text{ and } (11, 2, -11).$$

$$\mathbf{8} \quad \text{Given } C(-3, 2, -1) \text{ and } D(0, 1, -4), \quad \overrightarrow{CD} = \begin{pmatrix} 3 \\ -1 \\ -3 \end{pmatrix}$$

$\therefore$ the line passing through C and D has parametric equations

$$x = -3 + 3t, \quad y = 2 - t, \quad z = -1 - 3t$$

The line meets $2x - y + z = 3$ when $2(-3 + 3t) - (2 - t) + (-1 - 3t) = 3$
 $\therefore -6 + 6t - 2 + t - 1 - 3t = 3$
 $\therefore 4t = 12$
 $\therefore t = 3$

$\therefore$ they meet at $(6, -1, -10)$

9 $|\mathbf{a}| = 3, |\mathbf{b}| = \sqrt{7}$ and $\mathbf{a} \times \mathbf{b} = \begin{pmatrix} 1 \\ 2 \\ -3 \end{pmatrix}$

a $|\mathbf{a} \times \mathbf{b}| = |\mathbf{a}| |\mathbf{b}| \sin \theta$
 $\sqrt{1 + 4 + 9} = 3 \times \sqrt{7} \times \sin \theta$
 $\sin \theta = \frac{\sqrt{14}}{3\sqrt{7}} = \frac{\sqrt{2}}{3}$

But $\cos^2 \theta = 1 - \sin^2 \theta$

$\therefore \cos \theta = \pm \frac{\sqrt{7}}{3}$

Hence $\mathbf{a} \bullet \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos \theta$
 $= 3 \times \sqrt{7} \times (\pm \frac{\sqrt{7}}{3})$
 $= \pm 7$

b Area $\triangle OAB = \frac{1}{2} |\mathbf{a} \times \mathbf{b}|$
 $= \frac{1}{2} \sqrt{14} \text{ units}^2$

10 a The distance of $X(-1, 1, 3)$ from $x - 2y - 2z = 8$

is $d = \frac{|x_1 - 2y_1 - 2z_1 - 8|}{\sqrt{1^2 + (-2)^2 + (-2)^2}} = \frac{|-1 - 2 - 6 - 8|}{3} = \frac{|-17|}{3} = \frac{17}{3} \text{ units}$

b Since $2 - x = y - 3 = -\frac{1}{2}z$, $\frac{x - 2}{-1} = \frac{y - 3}{1} = \frac{z}{-2}$

$\therefore$ the line has direction vector $\mathbf{u} = \begin{pmatrix} -1 \\ 1 \\ -2 \end{pmatrix}$, and passes through $(2, 3, 0)$

$\therefore$ if P is a point on the line with coordinates $(2 - t, 3 + t, -2t)$, then

$$\overrightarrow{QP} = \begin{pmatrix} 2 - t - (-1) \\ 3 + t - 2 \\ -2t - 3 \end{pmatrix} = \begin{pmatrix} 3 - t \\ 1 + t \\ -2t - 3 \end{pmatrix}$$

If P is chosen such that $\overrightarrow{QP}$ is perpendicular to the line, then $\mathbf{u} \bullet \overrightarrow{QP} = 0$

$$\therefore \begin{pmatrix} -1 \\ 1 \\ -2 \end{pmatrix} \bullet \begin{pmatrix} 3 - t \\ 1 + t \\ -2t - 3 \end{pmatrix} = 0$$

$$\therefore -(3 - t) + 1(1 + t) - 2(-2t - 3) = 0$$

$$\therefore -3 + t + 1 + t + 4t + 6 = 0$$

$$\therefore 6t = -4$$

$$\therefore t = -\frac{2}{3}$$

$\therefore P$ is at $(2 + \frac{2}{3}, 3 - \frac{2}{3}, 2(\frac{2}{3}))$, so the foot of the perpendicular is at $(\frac{8}{3}, \frac{7}{3}, \frac{4}{3})$.

11 a $\overrightarrow{LM} = \begin{pmatrix} -2 \\ 2 \\ -2 \end{pmatrix} = -2 \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix}$

$\therefore$ since L lies on the line, it has parametric equations

$$x = 1 + t, \quad y = 0 - t, \quad z = 1 + t, \quad t \in \mathbb{R}$$

The line meets $x - 2y - 3z = 14$ if

$$(1 + t) - 2(-t) - 3(1 + t) = 14$$

$$\therefore 1 + t + 2t - 3 - 3t = 14$$

$$\therefore -2 = 14 \text{ which is absurd}$$

$\therefore$ the line and plane do not meet, but rather are parallel.

b The distance $d = \frac{|x_1 - 2y_1 - 3z_1 - 14|}{\sqrt{1 + 4 + 9}} = \frac{|1 - 2(0) - 3(1) - 14|}{\sqrt{14}} = \frac{16}{\sqrt{14}}$ units

12 a L_1 meets $2x + y - z = 2$

where $2(3t - 4) + (t + 2) - (2t - 1) = 2$

$\therefore 6t - 8 + t + 2 - 2t + 1 = 2$

$\therefore 5t = 7$

$\therefore t = \frac{7}{5}$

$\therefore$ the lines meet at

$\left(3\left(\frac{7}{5}\right) - 4, \frac{7}{5} + 2, 2\left(\frac{7}{5}\right) - 1\right)$

which is $\left(\frac{1}{5}, \frac{17}{5}, \frac{9}{5}\right)$

b L_1 meets L_2

where $3t - 4 = \frac{t + 2 - 5}{2} = \frac{-(2t - 1) - 1}{2}$

$\therefore 6t - 8 = t - 3 = -2t$

$\therefore 5t = 5$ and $3t = 3$

$\therefore t = 1$

So, L_1 and L_2 meet at $(-1, 3, 1)$.

c

$$\mathbf{n} = \begin{pmatrix} 3 \\ 1 \\ 2 \end{pmatrix} \times \begin{pmatrix} 1 \\ 2 \\ -2 \end{pmatrix} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 1 & 2 \\ 1 & 2 & -2 \end{vmatrix}$$

$$= \begin{vmatrix} 1 & 2 \\ 2 & -2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 3 & 2 \\ 1 & -2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 3 & 1 \\ 1 & 2 \end{vmatrix} \mathbf{k} = -6\mathbf{i} + 8\mathbf{j} + 5\mathbf{k}$$

$\therefore$ equation is $-6x + 8y + 5z = -6(-1) + 8(3) + 5(1)$

$\therefore -6x + 8y + 5z = 35$

$\therefore 6x - 8y - 5z = -35$

13 $x - 1 = \frac{y + 2}{2} = \frac{z - 3}{4}$ has direction vector $\begin{pmatrix} 1 \\ 2 \\ 4 \end{pmatrix}$ and $6x + 7y - 5z = 8$ has $\mathbf{n} = \begin{pmatrix} 6 \\ 7 \\ -5 \end{pmatrix}$.

Now $\begin{pmatrix} 1 \\ 2 \\ 4 \end{pmatrix} \cdot \begin{pmatrix} 6 \\ 7 \\ -5 \end{pmatrix} = 6 + 14 - 20 = 0$

$\therefore$ since these two vectors are perpendicular, the line is parallel to the plane.

Choose any point on the line, for example, $(1, -2, 3)$.

Then the distance from the line to the plane is $d = \frac{|6x_1 + 7y_1 - 5z_1 - 8|}{\sqrt{6^2 + 7^2 + (-5)^2}}$

$$= \frac{|6(1) + 7(-2) - 5(3) - 8|}{\sqrt{110}}$$

$$= \frac{31}{\sqrt{110}} \text{ units}$$

14 If A is $(3, -1, -2)$ and B $(5, 3, -4)$ then $\overrightarrow{AB} = \begin{pmatrix} 5 - 3 \\ 3 - (-1) \\ -4 - (-2) \end{pmatrix} = \begin{pmatrix} 2 \\ 4 \\ -2 \end{pmatrix} = 2 \begin{pmatrix} 1 \\ 2 \\ -1 \end{pmatrix}$

$\therefore$ the line has equation $\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 3 \\ -1 \\ -2 \end{pmatrix} + t \begin{pmatrix} 1 \\ 2 \\ -1 \end{pmatrix}, t \in \mathbb{R}$

and it meets $x^2 + y^2 + z^2 = 26$ where

$(3 + t)^2 + (-1 + 2t)^2 + (-2 - t)^2 = 26$

$\therefore 9 + 6t + t^2 + 1 - 4t + 4t^2 + 4 + 4t + t^2 - 26 = 0$

$\therefore 6t^2 + 6t - 12 = 0$

$\therefore t^2 + t - 2 = 0$

$\therefore (t + 2)(t - 1) = 0$

$\therefore t = -2$ or 1

$\therefore \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 3 \\ -1 \\ -2 \end{pmatrix} - 2 \begin{pmatrix} 1 \\ 2 \\ -1 \end{pmatrix} \text{ or } \begin{pmatrix} 3 \\ -1 \\ -2 \end{pmatrix} + \begin{pmatrix} 1 \\ 2 \\ -1 \end{pmatrix}$

$\therefore$ the line meets the sphere at $(1, -5, 0)$ and $(4, 1, -3)$.

15 a

Triangle ABC is isosceles.

 $\therefore$ line (AD) that meets the base at the midpoint, D, bisects the angle at A and is perpendicular to the base.

 The triangle ABD is right angled at D and angle DAB = 1° .

 $\therefore$ angle ABD = $180 - 90 - 1 = 89^\circ$.

 If line (AB) is extended to E, then angle DBE = $180 - 89 = 91^\circ$.

 Line (AB) is the arrow's intended path and line (BC) is the breeze, so the breeze is 91° to the intended direction of the arrow.

 ii The speed of the breeze is the length of (BC) = $2 \times |\overrightarrow{BD}|$.

$$\sin 1^\circ = \frac{|\overrightarrow{BD}|}{|\mathbf{v}|}$$

$$\therefore |\overrightarrow{BD}| = |\mathbf{v}| \sin 1^\circ$$

$$\therefore |\overrightarrow{BC}| = 2|\mathbf{v}| \sin 1^\circ$$

 So the speed of the breeze is $2|\mathbf{v}| \sin 1^\circ$.

 16 a X is $\left(\frac{4+10}{2}, \frac{4+2}{2}, \frac{-2+0}{2}\right)$ or $(7, 3, -1)$

$$\text{If D is } (a, b, c), \overrightarrow{AD} = \begin{pmatrix} a-1 \\ b-3 \\ c-4 \end{pmatrix} = \begin{pmatrix} a-1 \\ b-3 \\ c+4 \end{pmatrix} \text{ and } \overrightarrow{BC} = \begin{pmatrix} 6 \\ -2 \\ 2 \end{pmatrix}$$

$$\text{Since } \overrightarrow{AD} = \overrightarrow{BC}, \quad \begin{array}{lll} a-1=6, & b-3=-2, & c+4=2 \\ \therefore a=7, & b=1 & c=-2 \end{array} \quad \therefore \text{D is } (7, 1, -2)$$

$$\text{b } \overrightarrow{OY} = \overrightarrow{OA} + \overrightarrow{AY} = \begin{pmatrix} 1 \\ 3 \\ -4 \end{pmatrix} + \frac{2}{3} \overrightarrow{AX} = \begin{pmatrix} 1 \\ 3 \\ -4 \end{pmatrix} + \frac{2}{3} \begin{pmatrix} 7-1 \\ 3-3 \\ -1-4 \end{pmatrix}$$

$$\therefore \overrightarrow{OY} = \begin{pmatrix} 1 \\ 3 \\ -4 \end{pmatrix} + \frac{2}{3} \begin{pmatrix} 6 \\ 0 \\ 3 \end{pmatrix} = \begin{pmatrix} 5 \\ 3 \\ -2 \end{pmatrix} \text{ and so Y is } (5, 3, -2)$$

$$\text{c } \overrightarrow{BY} = \begin{pmatrix} 5-4 \\ 3-4 \\ -2-(-2) \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} \text{ and } \overrightarrow{BD} = \begin{pmatrix} 7-4 \\ 1-4 \\ -2-(-2) \end{pmatrix} = \begin{pmatrix} 3 \\ -3 \\ 0 \end{pmatrix}$$

$$\therefore \overrightarrow{BD} = 3\overrightarrow{BY} \quad \therefore \overrightarrow{BD} \parallel \overrightarrow{BY} \text{ and so B, D, and Y are collinear}$$

17 The system has augmented matrix:

$$\begin{aligned} & \left[\begin{array}{ccc|c} 1 & -1 & 1 & 5 \\ 2 & 1 & -1 & -1 \\ 7 & 2 & k & -k \end{array} \right] \\ & \sim \left[\begin{array}{ccc|c} 1 & -1 & 1 & 5 \\ 0 & 3 & -3 & -11 \\ 0 & 9 & k-7 & -k-35 \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - 2R_1 \\ R_3 \rightarrow R_3 - 7R_1 \end{array} \\ & \sim \left[\begin{array}{ccc|c} 1 & -1 & 1 & 5 \\ 0 & 3 & -3 & -11 \\ 0 & 0 & k+2 & -k-2 \end{array} \right] R_3 \rightarrow R_3 - 3R_2 \end{aligned}$$

Thus $(k+2)z = -(k+2)$

If $k \neq -2$ then $z = -1$, and as $3y - 3z = -11$,

$$\text{then } 3y = -14$$

$$\therefore y = -\frac{14}{3}$$

$$\text{and } x - y + z = 5,$$

$$\text{so } x = 5 - \frac{14}{3} + 1 = \frac{4}{3}$$

$\therefore$ we have three planes that meet at the unique point $(\frac{4}{3}, -\frac{14}{3}, -1)$.

If $k = -2$, then the 3 planes meet in a common line and hence there are an infinite number of solutions.

In this case, let $z = t$, $t \in \mathbb{R}$.

$$\text{Now } 3y - 3z = -11,$$

$$\therefore 3y = -11 + 3t$$

$$\therefore y = -\frac{11}{3} + t$$

$$\text{and as } x - y + z = 5$$

$$\therefore x = 5 + y - z$$

$$\therefore x = 5 - \frac{11}{3} + t - t$$

$$\therefore x = \frac{4}{3}$$

$$\therefore x = \frac{4}{3}, \quad y = -\frac{11}{3} + t, \quad z = t, \quad t \in \mathbb{R}$$

$$\mathbf{a} \quad \sin \theta = \frac{70}{350}$$

$$\therefore \theta \approx 11.5^\circ$$

So the pilot should face the plane 11.5° east of north.

$$\begin{aligned} \mathbf{b} \quad x^2 + 70^2 &= 350^2 \\ \therefore x^2 &= 350^2 - 70^2 \\ \therefore x &\approx 343 \text{ km h}^{-1} \end{aligned}$$

So the speed of the plane will be 343 km h^{-1} .

$$\therefore x_1(t) = 2 + t, \quad y_1(t) = 4 - 3t, \quad t \geq 0$$

$\mathbf{b}$ After time t has passed, submarine Y18's torpedo has been moving for time $(t - 2)$.

$$\therefore x_2(t) = 11 - (t - 2), \quad y_2(t) = 3 + a(t - 2)$$

$$\therefore x_2(t) = 13 - t, \quad y_2(t) = (3 - 2a) + at, \quad t \geq 2$$

$\mathbf{c}$ They meet where $2 + t = 13 - t$ and $4 - 3t = (3 - 2a) + at$

$$\therefore 2t = 11$$

$$\therefore -25 = 6 + 7a$$

$$\therefore 7a = -31$$

$$\therefore a = -\frac{31}{7}$$

Y18's torpedo has velocity vector $\begin{pmatrix} -1 \\ -\frac{31}{7} \end{pmatrix}$

$$\therefore \cos \theta = \frac{|2 + (-1) + (-4)|}{\sqrt{9}\sqrt{6}}$$

$$= \frac{3}{3\sqrt{6}} \quad \text{or} \quad \frac{1}{\sqrt{6}}$$

$$\therefore \theta \approx 65.9^\circ$$

8 a $\frac{x-8}{3} = \frac{y+9}{-16} = \frac{z-10}{7}$ has direction vector $\begin{pmatrix} 3 \\ -16 \\ 7 \end{pmatrix}$

$x = 15 + 3t, y = 29 + 8t, z = 5 - 5t$ has direction vector $\begin{pmatrix} 3 \\ 8 \\ -5 \end{pmatrix}$

$\therefore$ since the direction vectors are not scalar multiples of each other, the lines are not parallel.

If they intersect then $\frac{15+3t-8}{3} = \frac{29+8t+9}{-16} = \frac{5-5t-10}{7}$

$\therefore t + \frac{7}{3} = -\frac{1}{2}t - \frac{38}{16} = -\frac{5}{7}t - \frac{5}{7}$

Now $t + \frac{7}{3} = -\frac{1}{2}t - \frac{38}{16}$ requires $\frac{3}{2}t = -\frac{19}{8} - \frac{7}{3} = -\frac{113}{24} \therefore t = -\frac{113}{36}$

and $t + \frac{7}{3} = -\frac{5}{7}t - \frac{5}{7}$ requires $\frac{12}{7}t = -\frac{5}{7} - \frac{7}{3} = -\frac{64}{21} \therefore t = -\frac{16}{9}$

Hence the lines do not intersect, and since they are not parallel, they are skew.

b If θ is the acute angle between the two lines, and $\mathbf{v}_1$ and $\mathbf{v}_2$ are their direction vectors,

then $\cos \theta = \frac{|\mathbf{v}_1 \cdot \mathbf{v}_2|}{|\mathbf{v}_1||\mathbf{v}_2|} = \frac{\left| \begin{pmatrix} 3 \\ -16 \\ 7 \end{pmatrix} \cdot \begin{pmatrix} 3 \\ 8 \\ -5 \end{pmatrix} \right|}{\sqrt{3^2 + (-16)^2 + 7^2} \sqrt{3^2 + 8^2 + (-5)^2}}$

$\therefore \cos \theta = \frac{|9 - 128 - 35|}{\sqrt{314}\sqrt{98}} = \frac{154}{\sqrt{30772}}$

and so $\theta \approx 28.6^\circ$

c $\mathbf{v}_1 \times \mathbf{v}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & -16 & 7 \\ 3 & 8 & -5 \end{vmatrix} = \begin{vmatrix} -16 & 7 \\ 8 & -5 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 3 & 7 \\ 3 & -5 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 3 & -16 \\ 3 & 8 \end{vmatrix} \mathbf{k}$

$= 24\mathbf{i} + 36\mathbf{j} + 72\mathbf{k}$ or $12(2\mathbf{i} + 3\mathbf{j} + 6\mathbf{k})$

$\therefore \begin{pmatrix} 2 \\ 3 \\ 6 \end{pmatrix}$ is the normal of a plane containing L_1 and parallel to L_2 .

$\therefore$ the plane with normal $\begin{pmatrix} 2 \\ 3 \\ 6 \end{pmatrix}$ and containing L_2 also contains L_3 .

$\therefore$ the plane has equation $2x + 3y + 6z = 2(15) + 3(29) + 6(5)$

$\therefore 2x + 3y + 6z = 147$

d The shortest distance between L_1 and L_2 is the shortest distance between the plane containing L_2 and L_3 and a point on L_1 .

From **Exercise 15I** question **16 b**,

$= -16\mathbf{i} - 8\mathbf{j} - 4\mathbf{k}$ or $-4(4\mathbf{i} + 2\mathbf{j} + \mathbf{k})$

$\therefore$ the plane has equation $4x + 2y + z = 4(1) + 2(0) + 1(-1)$

$\therefore 4x + 2y + z = 3$

$$\therefore \text{ the vectors are } \begin{pmatrix} \sqrt{3} \\ -\sqrt{3} \\ \sqrt{3} \end{pmatrix} \text{ and } \begin{pmatrix} -\sqrt{3} \\ \sqrt{3} \\ -\sqrt{3} \end{pmatrix}.$$

b Any vector parallel to $\mathbf{i} + r\mathbf{j} + 3\mathbf{k}$ has the form $t \begin{pmatrix} 1 \\ r \\ 3 \end{pmatrix} = \begin{pmatrix} t \\ rt \\ 3t \end{pmatrix}$, $t \in \mathbb{R}$.

15 a Line 1 has direction vector $\begin{pmatrix} 1 \\ 2 \\ -1 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} 4 \\ 1 \\ -2 \end{pmatrix}$.

As one vector is not a scalar multiple of the other, the lines are not parallel.

$$\text{Now, } 2 + t = -8 + 4s \quad \dots (1) \quad -1 + 2t = s \quad \dots (2) \quad 3 - t = 7 - 2s \quad \dots (3)$$

Substituting (2) into (1), $2 + t = -8 + 4(-1 + 2t)$

$$\therefore 2 + t = -8 - 4 + 8t$$

$$\therefore 7t = 14$$

$$\therefore t = 2$$

$$\therefore s = -1 + 2(2) = 3$$

In (3), LHS = $3 - 2 = 1$ RHS = $7 - 2(3) = 1$ ✓

$\therefore s = 3, t = 2$ satisfies all three equations.

$\therefore$ the lines meet at $(4, 3, 1)$ {substituting $t = 2$ into line 1}

b Line 1 has direction vector $\begin{pmatrix} 1 \\ -2 \\ 3 \end{pmatrix}$ and line 2 has direction vector $\begin{pmatrix} -1 \\ 3 \\ 1 \end{pmatrix}$.

As one vector is not a scalar multiple of the other, the lines are not parallel.

$$\begin{array}{lll} \text{Now,} & 3 + t = 2 - s & 5 - 2t = 1 + 3s & -1 + 3t = 4 + s \\ & \therefore t + s = -1 \quad \dots (1) & 2t + 3s = 4 \quad \dots (2) & 3t - s = 5 \quad \dots (3) \end{array}$$

- 17 a** We substitute L_1 into the LHS of the plane's equation

$$2(-2t + 2) + (t) + (3t + 1) = -4t + 4 + t + 3t + 1 = 5 \quad \checkmark$$

$\therefore$ the plane contains the line.

- b** If $x + ky + z = 3$ contains L_1 then $(-2t + 2) + k(t) + 3t + 1 = 3$

$$\therefore t[-2 + k + 3] + 2 + 1 = 3$$

$$\therefore t[k + 1] = 0$$

$$\therefore k = -1 \text{ as } t \in \mathbb{R}$$

- c** From **a** and **b**, both $2x + y + z = 5$ and $x - y + z = 3$ contain L_1 .

So, substituting L_1 into plane 3 gives

$$-2(-2t + 2) + pt + 2(3t + 1) = q \text{ for all } t \in \mathbb{R}$$

$$\therefore 4t - 4 + pt + 6t + 2 = q \text{ for all } t \in \mathbb{R}$$

$$\therefore (10 + p)t - 2 = q \text{ for all } t$$

This equation has infinitely many solutions for t

when $10 + p = 0$ and $-2 = q$ {equating coefficients}

$$\therefore p = -10 \text{ and } q = -2$$

- 18 a** In augmented matrix form, the system is:

$$\left[\begin{array}{ccc|c} 1 & -3 & 2 & -5 \\ 3 & 1 & (2-k) & 10 \\ -2 & 6 & k & 5 \end{array} \right] \sim \left[\begin{array}{ccc|c} 1 & -3 & 2 & -5 \\ 0 & 10 & -4-k & 25 \\ 0 & 0 & k+4 & -5 \end{array} \right] \begin{array}{l} R_2 \rightarrow R_2 - 3R_1 \\ R_3 \rightarrow R_3 + 2R_1 \end{array}$$

$$\begin{array}{ccc|c} 3 & 1 & 2-k & 10 \\ -3 & 9 & -6 & 15 \\ \hline 0 & 10 & -4-k & 25 \\ -2 & 6 & k & 5 \\ 2 & -6 & 4 & -10 \\ \hline 0 & 0 & k+4 & -5 \end{array}$$

- b** If $k = -4$, row 3 becomes $0x + 0y + 0z = -5$

$\therefore$ the system is inconsistent and there are no solutions.

When $k = -4$ the system becomes

$$\begin{cases} x - 3y + 2z = -5 \\ 3x + y + 6z = 10 \\ -2x + 6y - 4z = 5 \end{cases} \quad \begin{array}{l} \text{Planes 1 and 3 are parallel.} \\ \text{In this case two planes are parallel and} \\ \text{they are intersected by the third plane.} \end{array}$$

- c i** There is a unique solution when $k \neq -4$.

- ii** If $k \neq -4$, then row 3 becomes $(k + 4)z = -5$

$$\therefore z = \frac{-5}{k + 4}$$

$$\text{and substituting in row 2 gives } 10y + -(4 + k) \left(\frac{-5}{k + 4} \right) = 25$$

$$\therefore 10y + 5 = 25$$

$$\therefore 10y = 20$$

$$\therefore y = 2$$

$$\text{and substituting in row 1 gives } x - 3(2) + 2\left(\frac{-5}{k+4}\right) = -5$$

$$\therefore x = 1 + \frac{10}{k+4}$$

$$\therefore \text{ the unique solution is } x = 1 + \frac{10}{k+4}, \quad y = 2, \quad z = \frac{-5}{k+4}.$$

In this case we have three planes which meet at a point.

$$\text{iii When } k = 1, \quad x = 1 + \frac{10}{1+4} = 3, \quad y = 2, \quad \text{and} \quad z = \frac{-5}{1+4} = -1$$

So, when $k = 1$ the unique solution is $(3, 2, -1)$.

$\therefore$ the angle between the two lines is about 70.5° .

- 6 a** Road A has direction vector $\begin{pmatrix} 15 - -9 \\ -16 - 2 \end{pmatrix} = \begin{pmatrix} 24 \\ -18 \end{pmatrix} = 6 \begin{pmatrix} 4 \\ -3 \end{pmatrix}$.

$$\text{So, Road A has equation } \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} -9 \\ 2 \end{pmatrix} + t \begin{pmatrix} 4 \\ -3 \end{pmatrix}, \quad t \in \mathbb{R}.$$

$$\text{So, Road B has equation } \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 6 \\ -18 \end{pmatrix} + s \begin{pmatrix} 5 \\ 12 \end{pmatrix}, \quad s \in \mathbb{R}.$$

- b** Let $A(-9 + 4t, 2 - 3t)$ be any point on Road A.

The closest point to $H(4, 11)$ on Road A is such that $\overrightarrow{HA} \perp \begin{pmatrix} 4 \\ -3 \end{pmatrix}$.

$$\therefore \begin{pmatrix} -13 + 4t \\ -9 - 3t \end{pmatrix} \cdot \begin{pmatrix} 4 \\ -3 \end{pmatrix} = 0$$

$$\begin{aligned} \therefore -52 + 16t + 27 + 9t &= 0 \\ \therefore 25t &= 25 \\ \therefore t &= 1 \end{aligned}$$

So A is $(-9 + 4, 2 - 3)$ or $(-5, -1)$.

$$\therefore \overrightarrow{HA} = \begin{pmatrix} -13 + 4 \\ -9 - 3 \end{pmatrix} = \begin{pmatrix} -9 \\ -12 \end{pmatrix}$$

The closest point to $H(4, 11)$ on Road B is such that $\overrightarrow{HB} \perp \begin{pmatrix} 5 \\ 12 \end{pmatrix}$.

$$\therefore \begin{pmatrix} 2 + 5s \\ -29 + 12s \end{pmatrix} \cdot \begin{pmatrix} 5 \\ 12 \end{pmatrix} = 0$$

$$\begin{aligned} \therefore 10 + 25s - 348 + 144s &= 0 \\ \therefore 169s &= 338 \\ \therefore s &= 2 \end{aligned}$$

So B is $(6 + 5(2), -18 + 12(2))$ or $(16, 6)$.

$$\therefore \overrightarrow{HB} = \begin{pmatrix} 2 + 5(2) \\ -29 + 12(2) \end{pmatrix} = \begin{pmatrix} 12 \\ -5 \end{pmatrix}$$

the line has equation

$$x = 2 + \lambda, y = 0 + 4\lambda, z = 1 - 3\lambda$$

12 a Given $A(-1, 3, 2)$ and the plane $2x - y + 2z = 8$,

the distance from A to the plane is $d = \frac{|2x_1 - y_1 + 2z_1 - 8|}{\sqrt{2^2 + (-1)^2 + 2^2}} = \frac{|2(-1) - 3 + 2(2) - 8|}{3} = \frac{|-9|}{3} = 3 \text{ units}$

b The point on the plane nearest A is the foot of the normal to the plane that passes through A.

Since the normal has direction vector $\begin{pmatrix} 2 \\ -1 \\ 2 \end{pmatrix}$ and passes through $(-1, 3, 2)$,

it has equation $x = -1 + 2t, y = 3 - t, z = 2 + 2t, t \in \mathbb{R}$

and meets the plane when $2(-1 + 2t) - (3 - t) + 2(2 + 2t) = 8$

$$\therefore -2 + 4t - 3 + t + 4 + 4t = 8$$

$$\therefore 9t = 9$$

c Suppose X is the foot of the perpendicular from A to the line, so X has coordinates $(7 - 2t, -6 + t, 1 + 5t)$ for some $t \in \mathbb{R}$. Then the shortest distance from A to the line is AX.

Now $\vec{AX} = \begin{pmatrix} 8 - 2t \\ t - 9 \\ -1 + 5t \end{pmatrix}$ and since the line has direction vector $\mathbf{u} = \begin{pmatrix} -2 \\ 1 \\ 5 \end{pmatrix}$,

$$\mathbf{u} \cdot \vec{AX} = 0$$

$$\begin{pmatrix} -2 \\ 1 \\ 5 \end{pmatrix} \cdot \begin{pmatrix} 8 - 2t \\ t - 9 \\ -1 + 5t \end{pmatrix} = 0$$

$$-16 + 4t + t - 9 - 5 + 25t = 0$$

$$\therefore 30t = 30$$

$$\therefore \mathbf{n} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -1 & -1 \\ 2 & 2 & -3 \end{vmatrix} = \begin{vmatrix} -1 & -1 \\ 2 & -3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & -1 \\ 2 & -3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & -1 \\ 2 & 2 \end{vmatrix} \mathbf{k} = \begin{pmatrix} 5 \\ 1 \\ 4 \end{pmatrix}$$

$\therefore$ since A lies on the plane it has equation $5x + y + 4z = 5(-1) + 0 + 4(2)$
 $\therefore 5x + y + 4z = 3$

b Since the normal has direction $\begin{pmatrix} 5 \\ 1 \\ 4 \end{pmatrix}$ and passes through $(0, 0, 0)$, it has equation

$$x = 0 + 5t, \quad y = 0 + t, \quad z = 0 + 4t$$

$$\therefore x = 5t, \quad y = t, \quad z = 4t, \quad t \in \mathbb{R}$$

c The line meets the plane when $5(5t) + t + 4(4t) = 3$
 $\therefore 25t + t + 16t = 3$
 $\therefore 42t = 3$
 $\therefore t = \frac{1}{14}$

So, the line meets the plane at $(\frac{5}{14}, \frac{1}{14}, \frac{2}{7})$.

14 a $\frac{x-3}{2} = \frac{y-4}{1} = \frac{z+1}{-2}$ has direction vector $\mathbf{v}_1 = \begin{pmatrix} 2 \\ 1 \\ -2 \end{pmatrix}$
 while $x = -1 + 3t, y = 2 + 2t, z = 3 - t$ has direction vector $\mathbf{v}_2 = \begin{pmatrix} 3 \\ 2 \\ -1 \end{pmatrix}$
 $\therefore$ the lines are not parallel.

If the lines intersect, then $\frac{-1+3t-3}{2} = \frac{2+2t-4}{1} = \frac{3-t+1}{-2}$

$$\therefore \frac{3}{2}t - 2 = 2t - 2 = \frac{t}{2} - 2$$

Now $t = 0$ satisfies this relation, so the lines intersect at $(-1, 2, 3)$.

b If θ is the acute angle between the lines, then

$$\cos \theta = \frac{|\mathbf{v}_1 \bullet \mathbf{v}_2|}{|\mathbf{v}_1||\mathbf{v}_2|} = \frac{|2 \times 3 + 1 \times 2 + -2 \times -1|}{\sqrt{9}\sqrt{14}} = \frac{|6 + 2 + 2|}{3\sqrt{14}} = \frac{10}{3\sqrt{14}}$$

$$\therefore \theta \approx 27.0^\circ$$

15 a The lines meet when

$$\frac{(15+3\lambda)-8}{3} = \frac{(29+8\lambda)+9}{-16} = \frac{(5-5\lambda)-10}{7} \quad \text{for some } \lambda \in \mathbb{R}$$

$$\therefore \frac{3\lambda+7}{3} = \frac{8\lambda+38}{-16} = \frac{-5\lambda-5}{7}$$

$$\therefore -48\lambda - 112 = 24\lambda + 114 \quad \text{and} \quad 56\lambda + 266 = 80\lambda + 80$$

$$\therefore -72\lambda = 226 \quad \text{and} \quad 186 = 24\lambda$$

$$\therefore \lambda = -\frac{113}{36} \quad \text{and} \quad \lambda = \frac{31}{4}$$

$\therefore$ no value of λ satisfies both equations.

$\therefore$ the lines do not meet.

Their direction vectors are $\begin{pmatrix} 3 \\ -16 \\ 7 \end{pmatrix}$ and $\begin{pmatrix} 3 \\ 8 \\ -5 \end{pmatrix}$ $\therefore$ they are not parallel.

$\therefore$ line 1 and line 2 are skew.

- b** Line 3 is parallel to line 1 and so has direction vector $\begin{pmatrix} 3 \\ -16 \\ 7 \end{pmatrix}$.

$\therefore$ the plane containing lines 2 and 3 has normal vector

$$\begin{aligned} \mathbf{n} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 8 & -5 \\ 3 & -16 & 7 \end{vmatrix} = \begin{vmatrix} 8 & -5 \\ -16 & 7 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 3 & -5 \\ 3 & 7 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 3 & 8 \\ 3 & -16 \end{vmatrix} \mathbf{k} \\ &= -24\mathbf{i} - 36\mathbf{j} - 72\mathbf{k} \\ &= -12(2\mathbf{i} + 3\mathbf{j} + 6\mathbf{k}) \end{aligned}$$

$\therefore$ the equation of the plane is $2x + 3y + 6z = 2(15) + 3(29) + 6(5)$

$$\therefore 2x + 3y + 6z = 147$$

- c** Since line 1 is parallel to line 3, line 1 is parallel to the plane containing lines 2 and 3.

$\therefore$ to find the shortest distance between lines 1 and 2, we choose a point on line 1 then find the shortest distance between this point and the plane.

$(8, -9, 10)$ is a point on line 1.

$$\begin{aligned} \therefore \text{distance } d &= \frac{|2(8) + 3(-9) + 6(10) - 147|}{\sqrt{2^2 + 3^2 + 6^2}} \\ &= \frac{|-98|}{\sqrt{49}} \\ &= \frac{98}{7} \\ &= 14 \text{ units} \end{aligned}$$

- d** Let the common perpendicular meet lines 1 and 2 at A and B respectively.

A is $(8 + 3\mu, -9 - 16\mu, 10 + 7\mu)$ for some $\mu \in \mathbb{R}$

B is $(15 + 3\lambda, 29 + 8\lambda, 5 - 5\lambda)$ for some $\lambda \in \mathbb{R}$

The common perpendicular has direction vector $\begin{pmatrix} 2 \\ 3 \\ 6 \end{pmatrix}$

$\therefore$ we need to find values for μ and λ so that

$$\overrightarrow{AB} = k \begin{pmatrix} 2 \\ 3 \\ 6 \end{pmatrix} \quad \text{for some scalar } k$$

$$\therefore \begin{pmatrix} 15 + 3\lambda - (8 + 3\mu) \\ 29 + 8\lambda - (-9 - 16\mu) \\ 5 - 5\lambda - (10 + 7\mu) \end{pmatrix} = k \begin{pmatrix} 2 \\ 3 \\ 6 \end{pmatrix}$$

$$\therefore \begin{pmatrix} 7 + 3\lambda - 3\mu \\ 38 + 8\lambda + 16\mu \\ -5 - 5\lambda - 7\mu \end{pmatrix} = \begin{pmatrix} 2k \\ 3k \\ 6k \end{pmatrix}$$

$$\therefore \begin{cases} 3\lambda - 3\mu - 2k = -7 \\ 8\lambda + 16\mu - 3k = -38 \\ -5\lambda - 7\mu - 6k = 5 \end{cases}$$

Solving simultaneously using technology gives $\lambda = -2$, $\mu = -1$, $k = 2$.

$\therefore$ A is $(8 + 3(-1), -9 - 16(-1), 10 + 7(-1))$

and B is $(15 + 3(-2), 29 + 8(-2), 5 - 5(-2))$

$\therefore$ the common perpendicular meets lines 1 and 2 at $(5, 7, 3)$ and $(9, 13, 15)$.

16 a The lines meet where

$$\begin{pmatrix} 3 \\ -2 \\ -2 \end{pmatrix} + s \begin{pmatrix} -1 \\ 1 \\ 2 \end{pmatrix} = \begin{pmatrix} 3 \\ 0 \\ -1 \end{pmatrix} + t \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix}$$

$$\therefore \begin{pmatrix} -s \\ s \\ 2s \end{pmatrix} = \begin{pmatrix} -t \\ -t+2 \\ t+1 \end{pmatrix}$$

$$\therefore \begin{cases} -s = -t & \Rightarrow s = t \quad \dots (1) \\ s = -t + 2 & \dots (2) \\ 2s = t + 1 & \dots (3) \end{cases}$$

Substituting (1) into (2) gives

$$t = -t + 2$$

$$\therefore 2t = 2$$

$$\therefore t = 1 \quad \text{and} \quad s = 1$$

Checking with (3): $2(1) = 1 + 1 \quad \checkmark$

$$\therefore \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 3 \\ -2 \\ -2 \end{pmatrix} + 1 \begin{pmatrix} -1 \\ 1 \\ 2 \end{pmatrix} = \begin{pmatrix} 2 \\ -1 \\ 0 \end{pmatrix}$$

$$\begin{aligned} \mathbf{n} = \overrightarrow{AB} \times \overrightarrow{AC} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -2 & -2 & 2 \\ 1 & -1 & -2 \end{vmatrix} = \begin{vmatrix} -2 & 2 \\ -1 & -2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} -2 & 2 \\ 1 & -2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} -2 & -2 \\ 1 & -1 \end{vmatrix} \mathbf{k} \\ &= 6\mathbf{i} - 2\mathbf{j} + 4\mathbf{k} \end{aligned}$$

Since $\mathbf{a} = \mathbf{b} = \mathbf{c}$, L_1 , L_2 , and L_3 are parallel.

When $s = 0$, the point on L_1 is $(1, 0, 2)$.

For L_2 , $y = t$, so the unique point on L_2 with y -coordinate 0 is the point where $t = 0$.

This point is $(16, 0, -\frac{4}{3})$.

For L_3 , $y = u$, so the unique point on L_3 with y -coordinate 0 is the point where $u = 0$.

This point is $(\frac{7}{2}, 0, \frac{3}{4})$.

$$(1, 0, 2) \neq (16, 0, -\frac{4}{3}), \quad (16, 0, -\frac{4}{3}) \neq (\frac{7}{2}, 0, \frac{3}{4}), \quad \text{and} \quad (1, 0, 2) \neq (\frac{7}{2}, 0, \frac{3}{4}).$$

$\therefore$ none of the lines are coincident.

3z is parallel to z and 3 times its length.

−2z is parallel to z, in the opposite direction and twice its length.

Reflect z in a horizontal line through the start of z.

Add −z to 3i.

Add −z to 2.

Reflect z in a horizontal line through the start of z and then add i.

Add z and 2 and find the vector $\frac{1}{3}$ of the length of the result.

Add z and −4 and find the vector $\frac{1}{2}$ of the length of the result.

6

Suppose $z = a + bi$, where $a, b \in \mathbb{R}$
 $\therefore z^* = a - bi$
 and $z + z^* = a + bi + a - bi$
 $= 2a$, which is real (since a is real)
 $\therefore z + z^*$ is always real for any complex number z .

7

Suppose $z = a + bi$, where $a, b \in \mathbb{R}$
 $\therefore z^* = a - bi$
 and $z - z^* = (a + bi) - (a - bi)$
 $= a + bi - a + bi$
 $= 2bi$

Since b is real, $z - z^*$ is purely imaginary for $b \neq 0$.
 If $b = 0$ then $z - z^* = 0$.
 $\therefore z - z^*$ is purely imaginary, unless z is real, then $z - z^* = 0$.

8

a

Let $z = a + bi$ and $w = c + di$
 $\therefore (z + w)^* = (a + bi + c + di)^*$
 $= ((a + c) + (b + d)i)^*$
 $= (a + c) - (b + d)i$
 $= a + c - bi - di$
 $= (a - bi) + (c - di)$
 $= z^* + w^*$
 $\therefore (z + w)^* = z^* + w^*$ for all complex z, w

b

Let $z = a + bi$ and $w = c + di$

$$\begin{aligned}
 \therefore (z - w)^* &= ((a + bi) - (c + di))^* \\
 &= (a + bi - c - di)^* \\
 &= ((a - c) + (b - d)i)^* \\
 &= (a - c) - (b - d)i \\
 &= a - c - bi + di \\
 &= (a - bi) - (c - di) \\
 &= z^* - w^*
 \end{aligned}$$

$$\therefore (z - w)^* = z^* - w^* \text{ for all complex } z, w$$

$$\mathbf{1} \quad \mathbf{a} \quad A(3, 6), \quad B(-1, 2), \quad z = 3 + 6i, \quad w = -1 + 2i$$

$$\begin{aligned} \mathbf{i} \quad & z - w = (3 + 6i) - (-1 + 2i) \\ & = 4 + 4i \\ & |z - w| = \sqrt{4^2 + 4^2} \\ & = \sqrt{32} \\ & = 4\sqrt{2} \\ & \therefore AB = 4\sqrt{2} \text{ units} \end{aligned}$$

$$\begin{aligned} \mathbf{ii} \quad & \frac{z+w}{2} = \frac{(3+6i) + (-1+2i)}{2} \\ & = \frac{2+8i}{2} \\ & = 1+4i \\ & \text{and so M is at } (1, 4) \end{aligned}$$

b $A(-4, 7), B(1, -3), z = -4 + 7i, w = 1 - 3i$

i $z - w = (-4 + 7i) - (1 - 3i)$
 $= -5 + 10i$

$$|z - w| = \sqrt{(-5)^2 + 10^2}$$

$$= \sqrt{125}$$

$$= 5\sqrt{5}$$

$\therefore AB = 5\sqrt{5}$ units

ii $\frac{z + w}{2} = \frac{(-4 + 7i) + (1 - 3i)}{2}$
 $= \frac{-3 + 4i}{2}$
 $= -\frac{3}{2} + 2i$

and so M is at $(-\frac{3}{2}, 2)$

2 a i $\overrightarrow{OQ} = z + w$ **ii** $\overrightarrow{PR} = w - z$

b In $\triangle OPQ$, $|z + w|$ represents the length of OQ, $|z|$ = length of OP, and $|w|$ the length of PQ. Now if w, z are not parallel, we will form the $\triangle OPQ$ and this means $OQ < OP + PQ$.

$\therefore |z + w| < |z| + |w|$

If w and z are parallel then we form a straight line and $OQ = OP + PQ$

$\therefore |z + w| = |z| + |w|$

Consequently $|z + w| \leq |z| + |w|$

c In $\triangle OPR$, the length of RP is represented by $|z - w|$. If w and z are not parallel, we form a triangle and $RP + OP > OR$. $\therefore |z - w| + |z| > |w|$

$\therefore |z - w| > |w| - |z|$

Equality will occur when w is parallel to z , in which case a straight line OPR is formed and

$|z - w| = |w| - |z|$

Consequently $|z - w| \geq |w| - |z|$

3 $z_1 \equiv \overrightarrow{OP_1}$ and $z_2 \equiv \overrightarrow{OP_2}$
 $\therefore z_1 - z_2 = \overrightarrow{OP_1} - \overrightarrow{OP_2}$
 $= \overrightarrow{OP_1} + \overrightarrow{P_2O}$ {since $\overrightarrow{P_2O} = -\overrightarrow{OP_2}$ }
 $= \overrightarrow{P_2O} + \overrightarrow{OP_1}$
 $= \overrightarrow{P_2P_1}$

- 4 a** $z \mapsto z^*$. Reflection in the real axis.
b $z \mapsto -z$. Rotation of π about O.
c $z \mapsto -z^*$. Reflection in the imaginary axis.
d $z \mapsto -iz$. Clockwise rotation of $\frac{\pi}{2}$ about O.

5 $\frac{50}{z^*} - \frac{10}{z} = 2 + 9i$ where $z = a + bi, a, b \in \mathbb{R}$

$\therefore 50z - 10z^* = (2 + 9i)(|z|^2)$ {multiply both sides by $zz^* = |z|^2$ }

$\therefore 50(a + bi) - 10(a - bi) = (2 + 9i)(40)$ { $|z| = 2\sqrt{10} \therefore |z|^2 = 40$ }

$\therefore 50a + 50bi - 10a + 10bi = 80 + 360i$

$\therefore 40a + 60bi = 80 + 360i$

Equating real and imaginary parts, $40a = 80$ and $60b = 360$

$\therefore a = 2$ and $b = 6$

$\therefore z = 2 + 6i$

e $\frac{z}{i} = \frac{3 \operatorname{cis} \theta}{\operatorname{cis}\left(\frac{\pi}{2}\right)}$

$$= 3 \operatorname{cis} \left(\theta - \frac{\pi}{2}\right)$$

$$\therefore \left| \frac{z}{i} \right| = 3 \quad \text{and} \quad \arg\left(\frac{z}{i}\right) = \theta - \frac{\pi}{2}$$

f $\frac{z}{1-i} = \frac{3 \operatorname{cis} \theta}{\sqrt{2} \operatorname{cis}\left(-\frac{\pi}{4}\right)}$

$$= \frac{3}{\sqrt{2}} \operatorname{cis} \left(\theta - \left(-\frac{\pi}{4}\right)\right)$$

$$= \frac{3}{\sqrt{2}} \operatorname{cis} \left(\theta + \frac{\pi}{4}\right)$$

$$\therefore \left| \frac{z}{1-i} \right| = \frac{3}{\sqrt{2}} \quad \text{and} \quad \arg\left(\frac{z}{1-i}\right) = \theta + \frac{\pi}{4}$$

7 a $z - 1 = z + (-1)$

$\therefore z - 1$ is represented
by the vector $\overrightarrow{OP}$

Considering the $\triangle OZP$

$$\begin{aligned}\widehat{PZO} &= \phi \quad \{\text{alternate angles}\} \\ OZ &= ZP = 1 \\ \therefore \triangle OPZ &\text{ is isosceles} \\ \therefore \widehat{POZ} &= \widehat{OPZ} = \alpha\end{aligned}$$

$$\therefore 2\alpha + \phi = \pi \text{ and so } \alpha = \frac{\pi - \phi}{2}$$

$$\begin{aligned}\therefore \arg(z - 1) &= \frac{\pi - \phi}{2} + \phi \\ &= \frac{\pi}{2} - \frac{\phi}{2} + \phi \\ &= \frac{\pi}{2} + \frac{\phi}{2} \dots (*)\end{aligned}$$

Using the cosine rule in $\triangle OZP$:

$$\begin{aligned}OP^2 &= 1^2 + 1^2 - 2(1)(1)\cos\phi \\ \therefore OP^2 &= 2 - 2\cos\phi \\ \therefore OP^2 &= 2 - 2\left(1 - 2\sin^2\left(\frac{\phi}{2}\right)\right) \\ \therefore OP^2 &= 2 - 2 + 4\sin^2\left(\frac{\phi}{2}\right) \\ \therefore OP^2 &= 4\sin^2\left(\frac{\phi}{2}\right) \\ \therefore |z - 1| &= 2\sin\left(\frac{\phi}{2}\right) \dots (**)\end{aligned}$$

b $z - 1 = 2\sin\left(\frac{\phi}{2}\right) \text{cis}\left(\frac{\pi}{2} + \frac{\phi}{2}\right) \quad \{\text{using } (*) \text{ and } (**)\}$

c $(z - 1)^* = 2\sin\left(\frac{\phi}{2}\right) \text{cis}\left(-\frac{\pi}{2} - \frac{\phi}{2}\right)$

8 a Now $z_2 - z_1 = \overrightarrow{AB}$
 $z_3 - z_2 = \overrightarrow{BC}$

b $\left| \frac{z_2 - z_1}{z_3 - z_2} \right| = \frac{|z_2 - z_1|}{|z_3 - z_2|}$
 $= \frac{|\overrightarrow{AB}|}{|\overrightarrow{BC}|}$

But $\triangle ABC$ is equilateral

$$\begin{aligned}\therefore |\overrightarrow{AB}| &= |\overrightarrow{BC}| \\ \therefore \left| \frac{z_2 - z_1}{z_3 - z_2} \right| &= 1\end{aligned}$$

c

$z_2 - z_1 = \overrightarrow{AB}$ and $z_3 - z_2 = \overrightarrow{BC}$ {from **a**}

$\therefore$ let $\arg(z_2 - z_1) = \alpha$
and $\arg(z_3 - z_2) = -\beta$ as shown

$$\begin{aligned}\therefore \arg\left(\frac{z_2 - z_1}{z_3 - z_2}\right) &= \arg(z_2 - z_1) - \arg(z_3 - z_2) \\ &= \alpha - (-\beta) \\ &= \alpha + \beta\end{aligned}$$

But $\widehat{ABC} = \frac{\pi}{3}$ since the triangle is equilateral

$\therefore \alpha + \beta + \frac{\pi}{3} = \pi$ {co-interior angles}

$\therefore \alpha + \beta = \frac{2\pi}{3}$

$\therefore \arg\left(\frac{z_2 - z_1}{z_3 - z_2}\right) = \frac{2\pi}{3}$

d From **b** and **c**, $\frac{z_2 - z_1}{z_3 - z_2} = 1 \text{cis}\left(\frac{2\pi}{3}\right)$

$$\begin{aligned}\therefore \left(\frac{z_2 - z_1}{z_3 - z_2}\right)^3 &= \left(\text{cis}\left(\frac{2\pi}{3}\right)\right)^3 \\ &= \text{cis}\left(\frac{2\pi}{3} + \frac{2\pi}{3} + \frac{2\pi}{3}\right) \\ &= \text{cis } 2\pi \\ &= 1\end{aligned}$$

$$9 \quad \tan \frac{\pi}{6} = \frac{1}{|a|}$$

$$\therefore |a| = \frac{1}{\tan \frac{\pi}{6}}$$

$$\therefore a = \pm\sqrt{3}$$

but from the graph, a is negative

$$\therefore a = -\sqrt{3}$$

$$\begin{aligned} \mathbf{c} \quad & 2.836\,49 \operatorname{cis}(-2.684\,32) = 2.836\,49(\cos(-2.684\,32) + i \sin(-2.684\,32)) \\ &\approx -2.55 - 1.25i \end{aligned}$$

2 Using technology

$$\begin{aligned} \mathbf{a} \quad & 3 - 4i \text{ has } r = \sqrt{3^2 + (-4)^2} \\ &= \sqrt{9 + 16} = \sqrt{25} = 5 \\ \therefore & \cos \theta = \frac{3}{5} \text{ and } \sin \theta = -\frac{4}{5} \\ \therefore & \theta = \arcsin\left(-\frac{4}{5}\right) \approx -0.927\,295\,218 \\ \therefore & 3 - 4i \approx 5 \operatorname{cis}(-0.927) \end{aligned}$$

8 a Since 1 is a root of $z^5 - 1 = 0$, we find that

$$z^5 - 1 = (z - 1)(1 + z + z^2 + z^3 + z^4)$$

$\therefore$ since α is a root,

$$(\alpha - 1)(1 + \alpha + \alpha^2 + \alpha^3 + \alpha^4) = 0$$

But $\alpha \neq 1$, so $1 + \alpha + \alpha^2 + \alpha^3 + \alpha^4 = 0$

$$1 \left| \begin{array}{ccccc|c} 1 & 0 & 0 & 0 & 0 & -1 \\ 0 & 1 & 1 & 1 & 1 & 1 \\ \hline 1 & 1 & 1 & 1 & 1 & 0 \end{array} \right.$$

or Note that $1 + \alpha + \alpha^2 + \alpha^3 + \alpha^4$ is the sum of a geometric series.

$$\text{Then } S_n = \frac{u_1(1 - r^n)}{1 - r} \text{ where } u_1 = 1, r = \alpha, n = 5$$

$$\therefore S_5 = \frac{1(1 - \alpha^5)}{1 - \alpha} \text{ and } \alpha^5 = \text{cis}(2\pi) = 1$$

$$\therefore 1 + \alpha + \alpha^2 + \alpha^3 + \alpha^4 = \frac{1(1 - 1)}{1 - \alpha} = 0$$

b Now if $\left(\frac{z + 2}{z - 1}\right)^5 = 1$ then $\frac{z + 2}{z - 1} = 1, \alpha, \alpha^2, \alpha^3, \text{ or } \alpha^4$ where $\alpha = \text{cis}\left(\frac{2\pi}{5}\right)$

$$\therefore \frac{z + 2}{z - 1} = \alpha^n \text{ where } n = 0, 1, 2, 3, 4$$

$$\therefore z + 2 = \alpha^n(z - 1)$$

$$\therefore z + 2 = \alpha^n z - \alpha^n$$

$$\therefore z(\alpha^n - 1) = \alpha^n + 2 \text{ and so } z = \frac{\alpha^n + 2}{\alpha^n - 1}$$

$$\therefore \text{roots of } \left(\frac{z + 2}{z - 1}\right)^5 = 1 \text{ are } \frac{\alpha + 2}{\alpha - 1}, \frac{\alpha^2 + 2}{\alpha^2 - 1}, \frac{\alpha^3 + 2}{\alpha^3 - 1}, \frac{\alpha^4 + 2}{\alpha^4 - 1}, \text{ where } \alpha = \text{cis}\left(\frac{2\pi}{5}\right)$$

Note: The case where $n = 0$ requires $\frac{z + 2}{z - 1} = 1$, and so $z + 2 = z - 1$, which has no solution.

9 Since $\left| \frac{z+1}{z-1} \right| = \frac{|z+1|}{|z-1|} = 1$, then $|z+1| = |z-1|$

Letting $z = x + iy$, $\therefore |(x+1) + iy| = |(x-1) + iy|$
 $\therefore \sqrt{(x+1)^2 + y^2} = \sqrt{(x-1)^2 + y^2}$

Squaring both sides, we get $(x+1)^2 + y^2 = (x-1)^2 + y^2$
 $\therefore x^2 + 2x + 1 = x^2 - 2x + 1$
 $\therefore 4x = 0$
 $\therefore x = 0$

Therefore since $z \neq 0$, z is purely imaginary.

$\therefore \phi + \phi + \theta = \pi$

$\therefore 2\phi = \pi - \theta$

$\phi = \frac{\pi}{2} - \frac{\theta}{2}$

13 Consider the diagram which shows vectors w , z , $z + w$, and $z - w$.

Clearly OABC is a parallelogram with $\overrightarrow{OB} = z + w$ and $\overrightarrow{CA} = z - w$

If $|z + w| = |z - w|$, the diagonals are equal in length.

Hence, OABC is actually a rectangle and so $\widehat{COA}$ is a right angle $\therefore \arg z$ and $\arg w$ differ by $\frac{\pi}{2}$.

$$\therefore \arg w = -\pi + \phi = -\frac{2\pi}{3}$$

iv $v = 4 \operatorname{cis}\left(\frac{2\pi}{3}\right)$, $w = 4 \operatorname{cis}\left(-\frac{2\pi}{3}\right)$

$$\therefore \frac{v^m w}{i} = \frac{\left(4 \operatorname{cis}\left(\frac{2\pi}{3}\right)\right)^m 4 \operatorname{cis}\left(-\frac{2\pi}{3}\right)}{\operatorname{cis}\left(\frac{\pi}{2}\right)}$$

$$= \frac{4^m \operatorname{cis}\left(\frac{2m\pi}{3}\right) 4 \operatorname{cis}\left(-\frac{2\pi}{3}\right)}{\operatorname{cis}\left(\frac{\pi}{2}\right)}$$

$$= 4^{m+1} \operatorname{cis}\left(\frac{2m\pi}{3} - \frac{2\pi}{3} - \frac{\pi}{2}\right)$$

$$\therefore \arg\left(\frac{v^m w}{i}\right) = \frac{2m\pi}{3} - \frac{2\pi}{3} - \frac{\pi}{2}$$

$$= \frac{4m\pi}{6} - \frac{4\pi}{6} - \frac{3\pi}{6}$$

$$= \frac{\pi(4m - 7)}{6}$$

v $\frac{v^m w}{i}$ is real when

$$\arg\left(\frac{v^m w}{i}\right) = 0 + k\pi, \quad k \in \mathbb{Z}$$

$$\therefore \frac{\pi(4m - 7)}{6} = k\pi$$

$$\therefore 4m - 7 = 6k$$

$$\therefore m = \frac{7 + 6k}{4}$$

One such value of m is

$$m = \frac{7}{4} \quad \{\text{when } k = 0\}$$

 $\therefore$ area of the n triangles $S_n = \frac{1}{2}nr^2 \sin\left(\frac{2\pi}{n}\right)$

- b i** As the number of triangles increases, the triangles cover more of the circle. As $n \rightarrow \infty$, the triangles get closer to covering the whole circle.

 $= -2 \sin A \sin B$

b $\cos S - \cos D = \cos(A+B) - \cos(A-B)$
 $= -2 \sin A \sin B \quad \{\text{using a}\}$

Now $S + D = A + B + A - B$ and $S - D = A + B - (A - B)$
 $= 2A \qquad \qquad \qquad = 2B$

$$\therefore A = \frac{S+D}{2} \qquad \qquad \qquad \therefore B = \frac{S-D}{2}$$

EXERCISE 17D

- b** The graph of $f(t)$ is not a straight line, so the jumper is not travelling with constant speed.

- If the *altitude* of the jumper is given by $f(t) = 452 - 4.8t^2$,
then the *distance* covered by the jumper $d(t) = 452 - f(t)$
 $\therefore d(t) = 452 - (452 - 4.8t^2)$
 $\therefore d(t) = 452 - 452 + 4.8t^2$
 $\therefore d(t) = 4.8t^2$

- i

We choose a fixed point F on $d(t)$ when $t = 0$
seconds. This is the point (0, 0).
We then choose another point M on the curve,
for example the point (1, 4.8).
The average speed in the interval $0 \leq t \leq 1$
is $\frac{4.8 - 0}{1 - 0} = 4.8 \text{ m s}^{-1}$.

We repeat this process, moving M closer to F each time, and get the following results:

t	gradient of [FM]
1	4.8
0.5	2.4
0.1	0.48
0.01	0.048
0.001	0.0048

So, as M approaches F, the gradient of [FM] approaches 0.
 $\therefore$ the speed of the jumper at $t = 0$ seconds is 0 m s^{-1} .

- ii

We now choose point F on $d(t)$ when $t = 1$
second. This is the point (1, 4.8).
We then choose another point M on the curve,
for example the point (2, 19.2).
The average speed in the interval $1 \leq t \leq 2$
is $\frac{19.2 - 4.8}{2 - 1} = 14.4 \text{ m s}^{-1}$.

We repeat this process, moving M closer to F each time, and get the following results:

t	gradient of [FM]
2	14.4
1.5	12
1.1	10.08
1.01	9.648
1.001	9.6048
1.0001	9.600 48

t	gradient of [FM]
0	4.8
0.5	7.2
0.9	9.12
0.99	9.552
0.999	9.5952
0.9999	9.599 52

So, as M approaches F (from either direction), the gradient of [FM] approaches 9.6.
 $\therefore$ the speed of the jumper at $t = 1$ second is 9.6 m s^{-1} .

- iii

We now choose point F on $d(t)$ when $t = 2$
seconds. This is the point (2, 19.2).
We then choose another point M on the curve,
for example the point (3, 43.2).
The average speed in the interval $2 \leq t \leq 3$
is $\frac{43.2 - 19.2}{3 - 2} = 24 \text{ m s}^{-1}$.

We repeat this process, moving M closer to F each time, and get the following results:

t	gradient of [FM]
3	24
2.5	21.6
2.1	19.68
2.01	19.248
2.001	19.2048
2.0001	19.200 48

t	gradient of [FM]
1	14.4
1.5	16.8
1.9	18.72
1.99	19.152
1.999	19.1952
1.9999	19.199 52

So, as M approaches F (from either direction), the gradient of [FM] approaches 19.2.
 $\therefore$ the speed of the jumper at $t = 2$ seconds is 19.2 m s^{-1} .

- iv** We choose a fixed point F on $d(t)$ when $t = 3$ seconds. This is the point (3, 43.2).
 We then choose another point M on the curve, for example the point (2, 19.2).
 The gradient of [MF] is

$$\frac{43.2 - 19.2}{3 - 2} = 24 \text{ m s}^{-1}.$$

We repeat this process, moving M closer to F each time, and get the following results:

So, as M approaches F, the gradient of [MF] approaches 28.8.

$\therefore$ the speed of the jumper at $t = 3$ seconds is 28.8 m s^{-1} .

t	gradient of [MF]
2	24
2.5	26.4
2.9	28.32
2.99	28.752
2.999	28.7952
2.9999	28.799 52

 The chord [AB] has gradient

$$\frac{x^2 - 4}{x - 2} \quad \left(\text{or} \quad \frac{4 - x^2}{2 - x} \right).$$

As B moves closer to A (from either side), we get the following results:

x	Point B	Gradient of [AB]
0	(0, 0)	2
1	(1, 1)	3
1.5	(1.5, 2.25)	3.5
1.9	(1.9, 3.61)	3.9
1.99	(1.99, 3.9601)	3.99
1.999	(1.999, 3.996 001)	3.999

x	Point B	Gradient of [AB]
5	(5, 25)	7
3	(3, 9)	5
2.5	(2.5, 6.25)	4.5
2.1	(2.1, 4.41)	4.1
2.01	(2.01, 4.0401)	4.01
2.001	(2.001, 4.004 001)	4.001

So, as B approaches A, the gradient of [AB] approaches 4.
 $\therefore$ the gradient of the tangent to $y = x^2$ at the point (2, 4) is 4.

b
$$\begin{aligned} \lim_{x \rightarrow 2} \frac{x^2 - 4}{x - 2} &= \lim_{x \rightarrow 2} \frac{(x + 2)(x - 2)}{x - 2} \\ &= \lim_{x \rightarrow 2} (x + 2) \quad \text{since } x \neq 2 \\ &= 4 \end{aligned}$$

This is the gradient of the tangent to $y = x^2$ at the point where $x = 2$.

EXERCISE 17E

- 1 a** $f(2) = 3$
- b** $f'(2)$ is the gradient of the tangent to $f(x)$ at the point where $x = 2$.
 Since $f(x)$ is a straight line, this is the same as the gradient of $f(x)$ itself.
 $f(x)$ is a horizontal line, and hence has gradient 0.
 $\therefore f'(2) = 0$
- 2 a** $f(0) = 4$
- b** $f'(0)$ is the gradient of the tangent to $f(x)$ at the point where $x = 0$.
 Since $f(x)$ is a straight line, this is the same as the gradient of $f(x)$ itself.
 $f(x)$ passes through $(0, 4)$ and $(4, 0)$, so it has gradient $= \frac{0 - 4}{4 - 0} = -1$
 $\therefore f'(0) = -1$
- 3** The graph shows the tangent to the curve $y = f(x)$ at the point where $x = 2$.
 The tangent passes through $(0, 1)$ and $(4, 5)$, so its gradient is $f'(2) = \frac{5 - 1}{4 - 0} = 1$.
 The equation of the tangent is $\frac{y - 1}{x - 0} = 1$
 $\therefore y = x + 1$
 When $x = 2$, $y = 3$, so the point of contact is $(2, 3)$.
 $\therefore f(2) = 3$ and $f'(2) = 1$.

When $x = -1$,
 $y = (-1)^3 - 3(-1) = 2$

When $x = 1$,
 $y = (1)^3 - 3(1) = -2$

So, the points on the graph at which the tangent has zero gradient are $(-1, 2)$ and $(1, -2)$.

b To find the speed of the jumper at $t = 2$ seconds, we need to find $f'(2)$.

Now $f'(t) = -9.6t$ {from **a**}

$$\therefore f'(2) = -9.6 \times 2 = -19.2$$

$\therefore$ the speed of the jumper at $t = 2$ seconds is 19.2 m s^{-1} .
(The $-$ sign indicates the jumper is moving downwards.)

6 a i

Suppose $P(\cos \theta, \sin \theta)$ lies on the unit circle in the first quadrant.

$[PQ]$ is drawn perpendicular to the x -axis, and arc QR with centre O is drawn. Now,

area of sector $OQR \leq \text{area } \triangle OQP \leq \text{area sector } OTP$

$$\therefore \frac{1}{2}(\text{OQ})^2 \times \theta \leq \frac{1}{2}(\text{OQ})(\text{PQ}) \leq \frac{1}{2}(\text{OT})^2 \times \theta$$

$$\therefore \frac{1}{2}\theta \cos^2 \theta \leq \frac{1}{2} \cos \theta \sin \theta \leq \frac{1}{2}\theta$$

Dividing throughout by $\frac{1}{2}\theta \cos \theta$, which is > 0 , $\cos \theta \leq \frac{\sin \theta}{\theta} \leq \frac{1}{\cos \theta}$

Now as $\theta \rightarrow 0$, both $\cos \theta \rightarrow 1$ and $\frac{1}{\cos \theta} \rightarrow 1$

$\therefore$ as $\theta \rightarrow 0^+$, $\frac{\sin \theta}{\theta} \rightarrow 1$. So, if $\theta > 0$ then $\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 1$.

ii If $f(\theta) = \frac{\sin \theta}{\theta}$, $f(-\theta) = \frac{\sin(-\theta)}{-\theta} = \frac{-\sin \theta}{-\theta} = \frac{\sin \theta}{\theta} = f(\theta)$

$\therefore \frac{\sin \theta}{\theta}$ is an even function, so as $\theta \rightarrow 0^-$, $\frac{\sin \theta}{\theta} \rightarrow 1$ also.

So, if $\theta < 0$, $\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 1$

b

Area of shaded segment

$$= (\text{area of sector}) - (\text{area of triangle})$$

$$= \frac{1}{2}r^2\theta - \frac{1}{2}r^2 \sin \theta$$

$$= \frac{1}{2}r^2(\theta - \sin \theta)$$

c As $\theta \rightarrow 0$, area of shaded segment $\rightarrow 0$

$$\therefore \frac{1}{2}r^2(\theta - \sin \theta) \rightarrow 0$$

$$\therefore \theta - \sin \theta \rightarrow 0$$

$$\therefore \theta \rightarrow \sin \theta$$

$$\therefore \frac{\sin \theta}{\theta} \rightarrow 1$$

$$\therefore \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 1$$

Differentiating both sides of $x + y = 8xy$ with respect to x ,

4 P_n is “if $y = Ae^{bx}$ where A and b are constants, then $\frac{d^n y}{dx^n} = b^n y$, for $n \in \mathbb{Z}^+$ ”.

Proof: (By the principle of mathematical induction)

$$(1) \text{ If } n = 1, \text{ LHS} = \frac{dy}{dx} = Ae^{bx} \times b = bAe^{bx} = by, \text{ RHS} = by \quad \therefore P_1 \text{ is true.}$$

$$(2) \text{ If } P_k \text{ is true, then } \frac{d^k y}{dx^k} = b^k y \text{ where } k \geq 1, k \in \mathbb{Z}^+.$$

$$\begin{aligned}\text{Now, } \frac{d^{k+1}y}{dx^{k+1}} &= \frac{d}{dx} \left(\frac{d^k y}{dx^k} \right) \\ &= \frac{d}{dx} (b^k y) \\ &= b^k \times \frac{d}{dx} (y) \quad \{\text{since } b^k \text{ is a constant}\} \\ &= b^k \times bAe^{bx} \\ &= b^{k+1} Ae^{bx} \\ &= b^{k+1} y\end{aligned}$$

Thus P_{k+1} is true whenever P_k is true and P_1 is true

6 $f(x) = 2x^3 - x$
 $\therefore f'(x) = 6x^2 - 1$
 $\therefore f''(x) = 12x$

By substituting the various values of x into these three functions, we can fill in the table as follows:

x	-1	0	1
$f(x)$	-	0	+
$f'(x)$	+	-	+
$f''(x)$	-	0	+

7 $f(x) = \frac{2}{3} \sin 3x$
 $\therefore f'(x) = \frac{2}{3} \times (\cos 3x) \times 3$
 $\qquad = 2 \cos 3x$
 $\therefore f''(x) = 2 \times (-\sin 3x) \times 3$
 $\qquad = -6 \sin 3x$
 $\therefore f^{(3)}(x) = -6 \times (\cos 3x) \times 3$
 $\qquad = -18 \cos 3x$
 $\therefore f^{(3)}\left(\frac{2\pi}{9}\right) = -18 \cos 3\left(\frac{2\pi}{9}\right)$
 $\qquad = -18 \cos\left(\frac{2\pi}{3}\right)$
 $\qquad = 9$

8 a $f(x) = 2 \sin^3 x - 3 \sin x$
 $\qquad = 2(\sin x)^3 - 3 \sin x$
 $\therefore f'(x) = 2 \times 3(\sin x)^2 \times (\cos x) - 3 \cos x$
 $\qquad = -3 \cos x(1 - 2 \sin^2 x)$
 $\qquad = -3 \cos x \cos 2x$
b $f''(x) = -3(-\sin x \times \cos 2x + \cos x \times (-2) \sin 2x)$
 $\qquad = 3 \sin x \cos 2x + 6 \cos x \sin 2x$

9 a $y = -\ln x$
 $\therefore \frac{dy}{dx} = -1 \times \frac{1}{x}$
 $\qquad = -x^{-1}$
 $\therefore \frac{d^2y}{dx^2} = -(-x^{-2})$
 $\qquad = x^{-2} = \frac{1}{x^2}$

b $y = x \ln x$ is the product of $u = x$ and $v = \ln x$
 $\therefore u' = 1$ and $v' = \frac{1}{x}$
Now $\frac{dy}{dx} = u'v + uv'$ {product rule}
 $\qquad = 1 \times \ln x + x \times \frac{1}{x}$
 $\qquad = \ln x + 1$
 $\therefore \frac{d^2y}{dx^2} = \frac{1}{x}$

c $y = (\ln x)^2$
 $\therefore \frac{dy}{dx} = 2(\ln x) \left(\frac{1}{x}\right) = \frac{2 \ln x}{x}$ which is a quotient with $u = 2 \ln x$ and $v = x$
 $\therefore u' = \frac{2}{x}$ and $v' = 1$
 $\therefore \frac{d^2y}{dx^2} = \frac{u'v - uv'}{v^2}$ {quotient rule}
 $\qquad = \frac{\frac{2}{x} \times x - 2 \ln x \times 1}{x^2}$
 $\qquad = \frac{2 - 2 \ln x}{x^2} = \frac{2}{x^2} (1 - \ln x)$

10 a $f(x) = x^2 - \frac{1}{x}$
 $\therefore f(1) = (1)^2 - \frac{1}{1}$
 $\qquad = 1 - 1$
 $\qquad = 0$

b $f(x) = x^2 - \frac{1}{x}$
 $\qquad = x^2 - x^{-1}$
 $\therefore f'(x) = 2x - (-x^{-2})$
 $\qquad = 2x + x^{-2}$
 $\qquad = 2x + \frac{1}{x^2}$
 $\therefore f'(1) = 2(1) + \frac{1}{1^2}$
 $\qquad = 2 + 1 = 3$

$$\begin{aligned} \therefore f^{(3)}(x) &= 6x^{-4} \\ &= \frac{6}{x^4} \end{aligned}$$

$$\therefore f^{(3)}(1) = \frac{6}{1^4} = 6$$

$$\begin{aligned} \text{Now } \frac{d^2y}{dx^2} - 7 \frac{dy}{dx} + 12y &= (18e^{3x} + 80e^{4x}) - 7(6e^{3x} + 20e^{4x}) + 12(2e^{3x} + 5e^{4x}) \\ &= 18e^{3x} + 80e^{4x} - 42e^{3x} - 140e^{4x} + 24e^{3x} + 60e^{4x} \\ &= e^{3x}[18 - 42 + 24] + e^{4x}[80 - 140 + 60] \\ &= e^{3x}(0) + e^{4x}(0) \\ &= 0 \end{aligned}$$

$$\therefore \frac{d^2y}{dx^2} - 7 \frac{dy}{dx} + 12y = 0$$

(1) For $n = 1$, $f'(x) = -e^{-x}(x+1)$ {using **a i**}
 $= (-1)^1 e^{-x}(x-1+2)$ $\therefore P_1$ is true.

(2) If P_k is true then $f^{(k)}(x) = (-1)^k e^{-x}(x - k + 2)$

Thus P_{k+1} is true whenever P_k is true

The gradient of the tangent is 2 where $6x^2 + 6x - 10 = 2$

$$\therefore 6x^2 + 6x - 12 = 0$$

So, the gradient of the tangent is 2 at $(-2, 19)$ and $(1, -2)$.

b Using technology, the point of intersection is (1, 2).

c If $y = e^{x-1} + 1$
 then $\frac{dy}{dx} = e^{x-1}$
 When $x = 1$, $\frac{dy}{dx} = e^{1-1} = e^0 = 1$
 $\therefore$ gradient of tangent = 1

If $y = 3 - e^{1-x}$
 then $\frac{dy}{dx} = -e^{1-x} \times -1 = e^{1-x}$
 When $x = 1$, $\frac{dy}{dx} = e^{1-1} = e^0 = 1$
 $\therefore$ gradient of tangent = 1

So, the tangents to each curve at (1, 2) both have a gradient of 1.

$$\mathbf{12} \quad f(x) = 2x^3 + Ax + B \quad \therefore f'(x) = 6x^2 + A$$

Now as the gradient at $(-2, 33)$ is 10,

Then, since $(-2, 33)$ lies on the curve,

$$\therefore f'(-2) = 10$$

$$f(-2) = 33$$

$$\therefore 10 = 6(-2)^2 + A$$

$$\therefore 2(-2)^3 - 14(-2) + B = 33$$

$$\therefore A = -14$$

$$\therefore -16 + 28 + B = 33$$

$$\therefore f(x) = 2x^3 - 14x + B$$

$$\therefore B = 21$$

$$\mathbf{13} \quad x^2 - 3y^2 = 0$$

$$\therefore 2x - 6y \frac{dy}{dx} = 0$$

$$\therefore \frac{dy}{dx} = \frac{x}{3y}$$

For any point (x, y) on $x^2 - 3y^2 = 0$, $\frac{dy}{dx}$ gives us the gradient of the tangent at that point.

Now $\frac{dy}{dx} = u'v + uv'$ {product rule}

If $\frac{dy}{dx} = 2e$, then $(1+x)e^x = 2e$

Solving by inspection, we find $x = 1$. When $x = 1$, $y = 1 \times e^1 = e$.

$\therefore$ the gradient of $y = xe^x$ is $2e$ at the point $(1, e)$.

So, the gradient of the curve at $x = 0$ is 0.

11 P_n is “If $y = x^n$, then $\frac{dy}{dx} = nx^{n-1}$ ”, $n \in \mathbb{Z}^+$.

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, then $y = x$. This has gradient 1, so $\frac{dy}{dx} = 1 = 1x^0$. $\therefore P_1$ is true.

(2) If P_k is true, then $y = x^k$ implies that $\frac{dy}{dx} = kx^{k-1}$

If $y = x^{k+1} = x^k x$,

$$\begin{aligned}
\text{then } \frac{dy}{dx} &= \frac{d}{dx} (x^k) x + x^k \frac{d}{dx} (x) \quad \{\text{product rule}\} \\

&= kx^k + x^k \\
&= (k + 1)x^k

Hence P_{k+1} is true whenever P_k is true, and P_1 is true

$\therefore P_n$ is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

12 a $y = uv$

$$\therefore \frac{dy}{dx} = \left(\frac{du}{dx}\right)v + u\left(\frac{dv}{dx}\right) \quad \{\text{product rule}\}$$

$$= \frac{du}{dx}vw + u\left(\frac{dv}{dx}w + v\frac{dw}{dx}\right) \quad \{\text{product rule}\}$$

$$= \frac{du}{dx}vw + u\frac{dv}{dx}w + uv\frac{dw}{dx}$$

13 a $f(x) = xe^{ax}$

$$f'(x) = e^{ax} + x(ae^{ax})$$

$$= e^{ax}(ax + 1)$$

$$f''(x) = ae^{ax}(ax + 1) + e^{ax}(a)$$

$$= ae^{ax}(ax + 1 + 1)$$

$$= ae^{ax}(ax + 2)$$

$$f'''(x) = a^2e^{ax}(ax + 2) + ae^{ax}(a)$$

$$= a^2e^{ax}(ax + 2 + 1)$$

$$= a^2e^{ax}(ax + 3)$$

$$f^{(4)}(x) = a^3e^{ax}(ax + 3) + a^2e^{ax}(a)$$

$$= a^3e^{ax}(ax + 3 + 1)$$

$$= a^3e^{ax}(ax + 4)$$

b $f^{(n)}(x) = a^{n-1}e^{ax}(ax + n)$

c P_n is “for $f(x) = xe^{ax}$, $f^{(n)}(x) = a^{n-1}e^{ax}(ax + n)$ ”, $n \in \mathbb{Z}^+$

Proof: (By the principle of mathematical induction)

(1) For $n = 1$, $f'(x) = e^{ax}(ax + 1)$ {using **a**}

$$= a^{1-1}e^{ax}(ax + 1) \quad \therefore P_1 \text{ is true.}$$

(2) If P_k is true then $f^{(k)}(x) = a^{k-1}e^{ax}(ax + k)$

$$\therefore f^{(k+1)}(x) = a^{k-1}(a)e^{ax}(ax + k) + a^{k-1}e^{ax}(a) \quad \{\text{product rule}\}$$

$$= a^ke^{ax}(ax + k) + a^ke^{ax}$$

$$= a^{(k+1)-1}e^{ax}(ax + [k + 1])$$

Thus P_{k+1} is true whenever P_k is true

$\therefore$ since P_1 is true, P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

Chapter 19

PROPERTIES OF CURVES

EXERCISE 19A

- 1 a** We seek the tangent to $y = x - 2x^2 + 3$ at $x = 2$.
When $x = 2$, $y = 2 - 2(2)^2 + 3 = -3$
 $\therefore$ the point of contact is $(2, -3)$.

$$\text{Now } \frac{dy}{dx} = 1 - 4x, \text{ so at } x = 2,$$

$$\frac{dy}{dx} = 1 - 8 = -7$$

$\therefore$ the tangent has equation

$$\frac{y - (-3)}{x - 2} = -7$$

$$\therefore y + 3 = -7(x - 2)$$

$$\therefore y = -7x + 14 - 3$$

$$\therefore y = -7x + 11$$

- c** We seek the tangent to $y = x^3 - 5x$ at $x = 1$.
When $x = 1$, $y = 1^3 - 5(1) = -4$
 $\therefore$ the point of contact is $(1, -4)$.

$$\text{Now } \frac{dy}{dx} = 3x^2 - 5, \text{ so at } x = 1,$$

$$\frac{dy}{dx} = 3 - 5 = -2$$

$\therefore$ the tangent has equation

$$\frac{y - (-4)}{x - 1} = -2$$

$$\therefore y + 4 = -2x + 2$$

$$\therefore y = -2x - 2$$

- e** We seek the tangent to $y = \frac{3}{x} - \frac{1}{x^2} = 3x^{-1} - x^{-2}$ at $(-1, -4)$.

$$\text{Now } \frac{dy}{dx} = -3x^{-2} + 2x^{-3}$$

$$= -\frac{3}{x^2} + \frac{2}{x^3} \text{ so at } x = -1,$$

$$\frac{dy}{dx} = -\frac{3}{(-1)^2} + \frac{2}{(-1)^3}$$

$$= -3 - 2$$

$$= -5$$

$\therefore$ the tangent has equation

$$\frac{y - (-4)}{x - (-1)} = -5$$

$$\therefore y + 4 = -5x - 5$$

$$\therefore y = -5x - 9$$

- b** We seek the tangent to $y = \sqrt{x} + 1 = x^{\frac{1}{2}} + 1$ at $x = 4$.
When $x = 4$, $y = \sqrt{4} + 1 = 3$
 $\therefore$ the point of contact is $(4, 3)$.

$$\text{Now } \frac{dy}{dx} = \frac{1}{2\sqrt{x}}, \text{ so at } x = 4,$$

$$\frac{dy}{dx} = \frac{1}{2\sqrt{4}} = \frac{1}{4}$$

$\therefore$ the tangent has equation

$$\frac{y - 3}{x - 4} = \frac{1}{4}$$

$$\therefore 4y - 12 = x - 4$$

$$\therefore 4y = x + 8$$

- d** We seek the tangent to $y = \frac{4}{\sqrt{x}}$ at $(1, 4)$.

$$\text{Now } y = \frac{4}{\sqrt{x}} = 4x^{-\frac{1}{2}}$$

$$\therefore \frac{dy}{dx} = -2x^{-\frac{3}{2}} \text{ so at } x = 1,$$

$$\frac{dy}{dx} = -2 \left(1^{-\frac{3}{2}} \right) = -2$$

$\therefore$ the tangent has equation

$$\frac{y - 4}{x - 1} = -2$$

$$\therefore y - 4 = -2x + 2$$

$$\therefore y = -2x + 6$$

- f** We seek the tangent to $y = 3x^2 - \frac{1}{x} = 3x^2 - x^{-1}$ at $x = -1$.
When $x = -1$, $y = 3(-1)^2 - \frac{1}{(-1)} = 4$
 $\therefore$ the point of contact is $(-1, 4)$.

$$\text{Now } \frac{dy}{dx} = 6x + x^{-2}$$

$$= 6x + \frac{1}{x^2} \text{ so at } x = -1,$$

$$\frac{dy}{dx} = 6(-1) + \frac{1}{(-1)^2} = -5$$

$\therefore$ the tangent has equation

$$\frac{y - 4}{x - (-1)} = -5$$

$$\therefore y - 4 = -5x - 5$$

$$\therefore y = -5x - 1$$

- 2 a** We seek the normal to $y = x^2$ at $(3, 9)$.

Now $\frac{dy}{dx} = 2x$ so at $x = 3$,

$$\frac{dy}{dx} = 2(3) = 6$$

$\therefore$ the normal at $(3, 9)$ has gradient $-\frac{1}{6}$,
so the equation of the normal is

$$\frac{y - 9}{x - 3} = -\frac{1}{6}$$

$$\therefore 6y - 54 = -x + 3$$

$$\therefore 6y = -x + 57$$

- c** We seek the normal to $y = \frac{5}{\sqrt{x}} - \sqrt{x}$ at $(1, 4)$.

Now $y = 5x^{-\frac{1}{2}} - x^{\frac{1}{2}}$

$$\therefore \frac{dy}{dx} = -\frac{5}{2}x^{-\frac{3}{2}} - \frac{1}{2}x^{-\frac{1}{2}} \text{ so at } x = 1,$$

$$\begin{aligned} \frac{dy}{dx} &= -\frac{5}{2} \left(1^{-\frac{3}{2}}\right) - \frac{1}{2} \left(1^{-\frac{1}{2}}\right) \\ &= -\frac{5}{2} - \frac{1}{2} = -3 \end{aligned}$$

$\therefore$ the normal at $(1, 4)$ has gradient $\frac{1}{3}$,
so the equation of the normal is

$$\frac{y - 4}{x - 1} = \frac{1}{3}$$

$$\therefore 3y - 12 = x - 1$$

$$\therefore 3y = x + 11$$

- 3 a** $y = 2x^3 + 3x^2 - 12x + 1$

$$\therefore \frac{dy}{dx} = 6x^2 + 6x - 12$$

Horizontal tangents have gradient $= 0$

$$\text{so } 6x^2 + 6x - 12 = 0$$

$$\therefore x^2 + x - 2 = 0$$

$$\therefore (x + 2)(x - 1) = 0$$

$$\therefore x = -2 \text{ or } x = 1$$

Now at $x = -2$,

$$\begin{aligned} y &= 2(-2)^3 + 3(-2)^2 - 12(-2) + 1 \\ &= 21 \end{aligned}$$

and at $x = 1$,

$$\begin{aligned} y &= 2(1)^3 + 3(1)^2 - 12(1) + 1 \\ &= -6 \end{aligned}$$

$\therefore$ the points of contact are $(-2, 21)$ and $(1, -6)$

$\therefore$ the tangents are $y = 21$ and $y = -6$.

- b** We seek the normal to $y = x^3 - 5x + 2$ at $x = -2$.

$$\text{When } x = -2, \quad y = (-2)^3 - 5(-2) + 2 = 4$$

and so the point of contact is $(-2, 4)$.

$$\text{Now } \frac{dy}{dx} = 3x^2 - 5 \text{ so at } x = -2,$$

$$\frac{dy}{dx} = 3(-2)^2 - 5 = 7$$

$\therefore$ the normal at $(-2, 4)$ has gradient $-\frac{1}{7}$,
so the equation of the normal is

$$\frac{y - 4}{x - (-2)} = -\frac{1}{7}$$

$$\therefore 7y - 28 = -(x + 2)$$

$$\therefore 7y = -x + 26$$

- d** We seek the normal to $y = 8\sqrt{x} - \frac{1}{x^2}$ at $x = 1$.

$$\text{When } x = 1, \quad y = 8\sqrt{1} - \frac{1}{1^2} = 7$$

$\therefore$ the point of contact is $(1, 7)$.

$$\text{Now } y = 8\sqrt{x} - \frac{1}{x^2} = 8x^{\frac{1}{2}} - x^{-2}$$

$$\therefore \frac{dy}{dx} = 4x^{-\frac{1}{2}} + 2x^{-3} \text{ so at } x = 1,$$

$$\frac{dy}{dx} = 4 + 2 = 6$$

$\therefore$ the normal at $(1, 7)$ has gradient $-\frac{1}{6}$,
so the equation of the normal is

$$\frac{y - 7}{x - 1} = -\frac{1}{6}$$

$$\therefore 6y - 42 = -x + 1$$

$$\therefore 6y = -x + 43$$

- b** Now $y = 2\sqrt{x} + \frac{1}{\sqrt{x}} = 2x^{\frac{1}{2}} + x^{-\frac{1}{2}}$

$$\therefore \frac{dy}{dx} = x^{-\frac{1}{2}} - \frac{1}{2}x^{-\frac{3}{2}} = \frac{1}{\sqrt{x}} - \frac{1}{2x\sqrt{x}}$$

Horizontal tangents have gradient $= 0$

$$\therefore \frac{1}{\sqrt{x}} - \frac{1}{2x\sqrt{x}} = 0$$

$$\therefore \frac{2x - 1}{2x\sqrt{x}} = 0$$

$$\therefore 2x - 1 = 0$$

$$\therefore x = \frac{1}{2}$$

Now at $x = \frac{1}{2}$,

$$\begin{aligned} y &= 2\sqrt{\frac{1}{2}} + \frac{1}{\sqrt{\frac{1}{2}}} = \frac{2\left(\frac{1}{2}\right) + 1}{\sqrt{\frac{1}{2}}} = \frac{2}{\sqrt{\frac{1}{2}}} \\ &= 2\sqrt{2} \end{aligned}$$

$\therefore$ the only horizontal tangent touches at the curve at $\left(\frac{1}{2}, 2\sqrt{2}\right)$.

c Now $y = 2x^3 + kx^2 - 3$

$$\therefore \frac{dy}{dx} = 6x^2 + 2kx$$

When $x = 2$, $\frac{dy}{dx} = 4$

$$\therefore 6(2)^2 + 2k(2) = 4$$

$$\therefore 24 + 4k = 4$$

$$\therefore 4k = -20$$

$$\therefore k = -5$$

d Now $y = 1 - 3x + 12x^2 - 8x^3$

$$\therefore \frac{dy}{dx} = -3 + 24x - 24x^2$$

When $x = 1$, $\frac{dy}{dx} = -3 + 24 - 24 = -3$

$\therefore$ the tangent at $(1, 2)$ has gradient -3

The tangents to the curve have gradient -3

when $-3 + 24x - 24x^2 = -3$

$$\therefore 24x^2 - 24x = 0$$

$$\therefore 24x(x - 1) = 0$$

$$\therefore \text{when } x = 0 \text{ or } x = 1$$

So the other x -value for which the tangent to the curve has gradient -3 is $x = 0$,

and when $x = 0$, $y = 1 - 0 + 0 - 0 = 1$

$\therefore$ the tangent to the curve at $(0, 1)$ is parallel to the tangent at $(1, 2)$.

This tangent has equation $\frac{y - 1}{x - 0} = -3$
or $y = -3x + 1$.

4 a Now $y = x^2 + ax + b$

$$\therefore \frac{dy}{dx} = 2x + a$$

At $x = 1$, $\frac{dy}{dx} = 2 + a$

$\therefore$ the gradient of the tangent to the curve at $x = 1$ will be $2 + a$.

However the equation of the tangent is

$$2x + y = 6 \text{ or } y = -2x + 6$$

and so the gradient of the tangent is -2 .

$$\therefore 2 + a = -2$$

$$\therefore a = -4$$

So, the curve is $y = x^2 - 4x + b$.

We also know that the tangent contacts the curve when $x = 1$.

$$\therefore 1^2 - 4(1) + b = -2(1) + 6$$

$$\therefore 1 - 4 + b = 4$$

$$\therefore b = 7$$

$$\therefore a = -4, \quad b = 7$$

c $y = 2x^2 - 1$

$$\therefore \frac{dy}{dx} = 4x$$

$$\therefore \text{at the point where } x = a, \quad \frac{dy}{dx} = 4a$$

$\therefore$ the gradient of the tangent at the point where $x = a$ is $4a$.

Also, at $x = a$, $y = 2a^2 - 1$.

$\therefore$ the tangent has equation

$$\frac{y - (2a^2 - 1)}{x - a} = 4a$$

$$\therefore y - 2a^2 + 1 = 4a(x - a)$$

$$\therefore y - 2a^2 + 1 = 4ax - 4a^2$$

$$\therefore 4ax - y = 2a^2 + 1$$

b Now $y = a\sqrt{x} + \frac{b}{\sqrt{x}} = ax^{\frac{1}{2}} + bx^{-\frac{1}{2}}$

$$\therefore \frac{dy}{dx} = \frac{a}{2}x^{-\frac{1}{2}} - \frac{b}{2}x^{-\frac{3}{2}}$$

$$\begin{aligned} \therefore \text{at } x = 4, \quad \frac{dy}{dx} &= \frac{a}{2} \left(4^{-\frac{1}{2}}\right) - \frac{b}{2} \left(4^{-\frac{3}{2}}\right) \\ &= \frac{a}{2} \left(\frac{1}{2}\right) - \frac{b}{2} \left(\frac{1}{8}\right) \\ &= \frac{a}{4} - \frac{b}{16} \end{aligned}$$

$\therefore$ the gradient of the tangent to the curve at

$$x = 4 \text{ will be } \frac{a}{4} - \frac{b}{16} = \frac{4a - b}{16}$$

However the equation of the *normal* is

$$4x + y = 22 \text{ or } y = -4x + 22.$$

$\therefore$ the normal has gradient -4 .

$\therefore$ the tangent has gradient $\frac{1}{4}$, and so

$$\frac{4a - b}{16} = \frac{1}{4}$$

$$\therefore 4a - b = 4$$

$$\therefore b = 4a - 4 \quad \dots (1)$$

Also, at $x = 4$ the normal line intersects the curve.

$$\therefore a\sqrt{4} + \frac{b}{\sqrt{4}} = -4(4) + 22$$

$$\therefore 2a + \frac{b}{2} = 6$$

Consequently, $2a + \frac{4a - 4}{2} = 6$ {using (1)}

$$\therefore 2a + 2a - 2 = 6$$

$$\therefore 4a = 8$$

$$\therefore a = 2$$

and so $b = 4(2) - 4 = 4$ {from (1)}

$$\therefore a = 2, \quad b = 4$$

5 a $y = \sqrt{2x+1} = (2x+1)^{\frac{1}{2}}$

When $x = 4$, $y = \sqrt{2(4)+1} = 3$,
so the point of contact is $(4, 3)$.

Now $\frac{dy}{dx} = \frac{1}{2}(2x+1)^{-\frac{1}{2}}(2)$ {chain rule}

$$= \frac{1}{\sqrt{2x+1}}$$

$$\therefore \text{ at } x = 4, \quad \frac{dy}{dx} = \frac{1}{\sqrt{2(4)+1}} = \frac{1}{3}$$

$$\therefore \text{ the tangent has equation } \frac{y-3}{x-4} = \frac{1}{3}$$

$$\therefore 3y - 9 = x - 4$$

$$\therefore 3y = x + 5$$

c We seek the tangent to $f(x) = \frac{x}{1-3x}$ at $(-1, -\frac{1}{4})$.

$f(x)$ is a quotient where

$$u = x \quad \text{and} \quad v = 1 - 3x$$

$$\therefore u' = 1 \quad \text{and} \quad v' = -3$$

Now $f'(x) = \frac{u'v - uv'}{v^2}$ {quotient rule}

$$\therefore f'(x) = \frac{1(1-3x) - x(-3)}{(1-3x)^2}$$

$$= \frac{1}{(1-3x)^2}$$

$$\therefore f'(-1) = \frac{1}{(1-3(-1))^2} = \frac{1}{16}$$

$$\therefore \text{ tangent has equation } \frac{y - (-\frac{1}{4})}{x - (-1)} = \frac{1}{16}$$

$$\therefore 16y + 4 = x + 1$$

$$\therefore 16y = x - 3$$

6 a We seek the normal to $y = \frac{1}{(x^2+1)^2}$ at $(1, \frac{1}{4})$.

As $y = (x^2+1)^{-2}$,

$$\frac{dy}{dx} = -2(x^2+1)^{-3}(2x) = \frac{-4x}{(x^2+1)^3}$$

$$\therefore \text{ at } x = 1, \quad \frac{dy}{dx} = \frac{-4}{(1+1)^3} = \frac{-4}{8} = -\frac{1}{2}$$

$\therefore$ the normal at $(1, \frac{1}{4})$ has gradient 2.

So the equation of the normal is

$$\frac{y - \frac{1}{4}}{x - 1} = 2$$

$$\therefore y - \frac{1}{4} = 2x - 2$$

$$\therefore y = 2x - \frac{7}{4}$$

b $y = \frac{1}{2-x} = (2-x)^{-1}$

$$\therefore \text{ at } x = -1, \quad y = \frac{1}{2 - (-1)} = \frac{1}{3}$$

So the point of contact is $(-1, \frac{1}{3})$.

Now $\frac{dy}{dx} = -1(2-x)^{-2}(-1)$ {chain rule}

$$= \frac{1}{(2-x)^2}$$

$$\therefore \text{ at } x = -1, \quad \frac{dy}{dx} = \frac{1}{(2 - (-1))^2} = \frac{1}{9}$$

$$\therefore \text{ tangent has equation } \frac{y - \frac{1}{3}}{x - (-1)} = \frac{1}{9}$$

$$\therefore 9y - 3 = x + 1$$

$$\therefore 9y = x + 4$$

d We seek the tangent to $f(x) = \frac{x^2}{1-x}$ at $(2, -4)$.

$f(x)$ is a quotient where

$$u = x^2 \quad \text{and} \quad v = 1 - x$$

$$\therefore u' = 2x \quad \text{and} \quad v' = -1$$

Now $f'(x) = \frac{u'v - uv'}{v^2}$ {quotient rule}

$$\therefore f'(x) = \frac{2x(1-x) - x^2(-1)}{(1-x)^2}$$

$$= \frac{2x - 2x^2 + x^2}{(1-x)^2} = \frac{2x - x^2}{(1-x)^2}$$

$$\therefore f'(2) = \frac{2(2) - 2^2}{(1-2)^2} = \frac{4-4}{1} = 0$$

As the tangent has gradient 0, it is horizontal.

$\therefore$ its equation is $y = c$

Since the contact point is $(2, -4)$, the tangent has equation $y = -4$.

b $y = \frac{1}{\sqrt{3-2x}}$

$$\therefore \text{ at } x = -3, \quad y = \frac{1}{\sqrt{3-2(-3)}} = \frac{1}{3}$$

$\therefore$ the point of contact is $(-3, \frac{1}{3})$

Now $y = (3-2x)^{-\frac{1}{2}}$

$$\therefore \frac{dy}{dx} = -\frac{1}{2}(3-2x)^{-\frac{3}{2}}(-2) = (3-2x)^{-\frac{3}{2}}$$

$$\therefore \text{ at } x = -3, \quad \frac{dy}{dx} = (3-2(-3))^{-\frac{3}{2}}$$

$$= 9^{-\frac{3}{2}} = 3^{-3} = \frac{1}{27}$$

$\therefore$ the normal at $(-3, \frac{1}{3})$ has gradient -27 .

So the equation of the normal is

$$\frac{y - \frac{1}{3}}{x - (-3)} = -27$$

$$\therefore y - \frac{1}{3} = -27(x+3)$$

$$\therefore y = -27x - \frac{242}{3}$$

c $f(x) = \sqrt{x}(1-x)^2$

Since $f(4) = \sqrt{4}(1-4)^2 = 18$,
the point of contact is $(4, 18)$.

Now $f(x)$ is a product where

$$u = x^{\frac{1}{2}} \quad \text{and} \quad v = (1-x)^2$$

$$\therefore u' = \frac{1}{2}x^{-\frac{1}{2}} \quad \text{and} \quad v' = 2(1-x)(-1) = -2(1-x)$$

Now $f'(x) = u'v + uv'$ {product rule}

$$\therefore f'(x) = \frac{1}{2}x^{-\frac{1}{2}}(1-x)^2 - x^{\frac{1}{2}}2(1-x)$$

$$\therefore f'(4) = \frac{1}{2\sqrt{4}}(1-4)^2 - \sqrt{4}(2)(1-4)$$

$$= \frac{1}{4}(9) - 2(2)(-3) = \frac{57}{4}$$

$\therefore$ the normal at $(4, 18)$ has gradient $-\frac{4}{57}$.

So, the equation of the normal is

$$\frac{y-18}{x-4} = -\frac{4}{57}$$

$$\therefore 57(y-18) = -4(x-4)$$

$$\therefore 57y = -4x + 1042$$

d $f(x) = \frac{x^2-1}{2x+3}$

Since $f(-1) = \frac{(-1)^2-1}{2(-1)+3} = \frac{0}{1} = 0$,

the point of contact is $(-1, 0)$.

Now $f(x)$ is a quotient where

$$u = x^2 - 1 \quad \text{and} \quad v = 2x + 3$$

$$\therefore u' = 2x \quad \text{and} \quad v' = 2$$

Now $f'(x) = \frac{u'v - uv'}{v^2}$

$$= \frac{2x(2x+3) - (x^2-1)(2)}{(2x+3)^2}$$

$$\therefore f'(-1) = \frac{2(-1)(-2+3) - ((-1)^2-1)(2)}{(2(-1)+3)^2}$$

$$= \frac{-2(1) - (0)(2)}{(1)^2} = -2$$

$\therefore$ the normal at $(-1, 0)$ has gradient $\frac{1}{2}$.

So, the equation of the normal is

$$\frac{y-0}{x-(-1)} = \frac{1}{2}$$

or $2y = x + 1$

7 The tangent has equation $3x + y = 5$ or $y = -3x + 5$

$\therefore$ the tangent has gradient -3 (1)

Also, at $x = -1$, $y = -3(-1) + 5 = 8$

$\therefore$ the tangent contacts the curve at $(-1, 8)$ (2)

Now $y = a(1-bx)^{\frac{1}{2}}$, so $\frac{dy}{dx} = \frac{1}{2}a(1-bx)^{-\frac{1}{2}}(-b)$

$$\therefore -3 = \frac{1}{2}a(1+b)^{-\frac{1}{2}}(-b) \quad \{\text{using (1)}\}$$

$$\therefore 6 = \frac{ab}{\sqrt{1+b}} \quad \dots (3)$$

Using (2), $(-1, 8)$ must lie on the curve $y = a\sqrt{1-bx}$

$$\therefore 8 = a\sqrt{1+b} \quad \dots (4)$$

$$\therefore \frac{6\sqrt{1+b}}{b} = \frac{8}{\sqrt{1+b}} \quad \{\text{equating as in (3) and (4)}\}$$

$$\therefore 6(1+b) = 8b$$

$$\therefore 6 + 6b = 8b$$

$$\therefore 6 = 2b$$

$$\therefore b = 3 \quad \text{and} \quad a = \frac{8}{\sqrt{4}} = 4$$

8 $f: x \mapsto \frac{x}{\sqrt{2-x}}$

a f is defined when $2-x > 0$

$$\therefore x < 2$$

$\therefore$ domain of f is $\{x \mid x < 2\}$

$$\mathbf{b} \quad f(x) = \frac{x}{\sqrt{2-x}}$$

Now $f(x)$ is a quotient where

$$u = x \quad \text{and} \quad v = (2-x)^{\frac{1}{2}}$$

$$\therefore u' = 1 \quad \text{and} \quad v' = \frac{1}{2}(2-x)^{-\frac{1}{2}}(-1)$$

$$\begin{aligned} \text{Now } f'(x) &= \frac{u'v - uv'}{v^2} \\ &= \frac{1(2-x)^{\frac{1}{2}} - x\frac{1}{2}(2-x)^{-\frac{1}{2}}(-1)}{(2-x)^{\frac{2}{2}}} \\ &= \frac{\frac{2(2-x)}{2(2-x)^{\frac{1}{2}}} + \frac{x}{2(2-x)^{\frac{1}{2}}}}{(2-x)^{\frac{2}{2}}} \\ &= \frac{2(2-x) + x}{2(2-x)^{\frac{3}{2}}} \\ &= \frac{4-2x+x}{2(2-x)^{\frac{3}{2}}} \\ &= \frac{4-x}{2(2-x)^{\frac{3}{2}}} \end{aligned}$$

$$\mathbf{c} \quad f(x) = \frac{x}{\sqrt{2-x}} = -1$$

$$\therefore x = -\sqrt{2-x}$$

$$\therefore x^2 = 2-x$$

$$\therefore x^2 + x - 2 = 0$$

$$\therefore (x+2)(x-1) = 0$$

$$\therefore x = -2 \text{ or } 1$$

$$\text{but } x < 2 \quad \therefore x = -2$$

$\therefore$ the point of contact is $(-2, -1)$.

$$\begin{aligned} \text{Now } f'(-2) &= \frac{4 - (-2)}{2(2 - (-2))^{\frac{3}{2}}} \\ &= \frac{4+2}{2(4)^{\frac{3}{2}}} \\ &= \frac{6}{2(2)^3} \\ &= \frac{3}{8} \end{aligned}$$

$\therefore$ the normal at $(-2, -1)$ has gradient $-\frac{8}{3}$.

So, the equation of the normal is

$$\frac{y - (-1)}{x - (-2)} = -\frac{8}{3}$$

$$\therefore 3(y+1) = -8(x+2)$$

$$\therefore 3y+3 = -8x-16$$

$$\therefore 8x+3y = -19$$

$$\mathbf{9} \quad \mathbf{a} \quad f(x) = e^{-x}$$

$$\therefore f(1) = e^{-1}$$

$\therefore$ the point of contact is $\left(1, \frac{1}{e}\right)$.

$$\text{Now } f'(x) = -e^{-x}$$

$$\therefore f'(1) = -e^{-1} = -\frac{1}{e}$$

So, the gradient of the tangent is $-\frac{1}{e}$

$$\therefore \text{ the tangent has equation } \frac{y - \frac{1}{e}}{x - 1} = -\frac{1}{e}$$

$$\therefore e\left(y - \frac{1}{e}\right) = -(x-1)$$

$$\therefore ey - 1 = -x + 1$$

$$\therefore x + ey = 2$$

$$\text{or } y = -\frac{1}{e}x + \frac{2}{e}$$

$$\mathbf{b} \quad y = \ln(2-x)$$

so when $x = -1$, $y = \ln 3$

$\therefore$ the point of contact is $(-1, \ln 3)$.

$$\text{Now } \frac{dy}{dx} = \frac{-1}{2-x}$$

$$\therefore \text{ when } x = -1, \frac{dy}{dx} = -\frac{1}{2+1} = -\frac{1}{3}$$

So, the gradient of the tangent is $-\frac{1}{3}$.

$$\therefore \text{ the tangent has equation } \frac{y - \ln 3}{x + 1} = -\frac{1}{3}$$

$$\therefore 3(y - \ln 3) = -(x + 1)$$

$$\therefore 3y - 3\ln 3 = -x - 1$$

$$\therefore x + 3y = 3\ln 3 - 1$$

$$\mathbf{c} \quad y = \ln \sqrt{x} \quad \therefore \text{ when } y = -1, -1 = \frac{1}{2} \ln x$$

$$= \ln x^{\frac{1}{2}} \quad \therefore \ln x = -2$$

$$\therefore x = e^{-2}$$

$$= \frac{1}{2} \ln x$$

$$\therefore x = \frac{1}{e^2}$$

$\therefore$ the point of contact is $\left(\frac{1}{e^2}, -1\right)$

Now $\frac{dy}{dx} = \frac{1}{2} \left(\frac{1}{x} \right) = \frac{1}{2x}$, so at the point of contact, $\frac{dy}{dx} = \frac{1}{2e^{-2}} = \frac{e^2}{2}$

$\therefore$ the tangent has gradient $\frac{e^2}{2}$ and the normal has gradient $-\frac{2}{e^2}$

$\therefore$ the normal has equation $\frac{y+1}{x-\frac{1}{e^2}} = -\frac{2}{e^2}$

$$\therefore e^2(y+1) = -2 \left(x - \frac{1}{e^2} \right)$$

$$\therefore e^2y + e^2 = -2x + \frac{2}{e^2}$$

$$\therefore 2x + e^2y = \frac{2}{e^2} - e^2 \quad \text{or} \quad y = -\frac{2}{e^2}x + \frac{2}{e^4} - 1$$

10 $y = \frac{\cos x}{1 + \sin x}$

Now since y is a quotient where $u = \cos x$ and $v = 1 + \sin x$
 $\therefore u' = -\sin x$ and $v' = \cos x$

$$\begin{aligned} \text{So } \frac{dy}{dx} &= \frac{u'v - uv'}{v^2} \\ &= \frac{(-\sin x)(1 + \sin x) - \cos x(\cos x)}{(1 + \sin x)^2} \\ &= \frac{-\sin x - \sin^2 x - \cos^2 x}{(1 + \sin x)^2} \\ &= \frac{-1 - \sin x}{(1 + \sin x)^2} \quad \{\sin^2 x + \cos^2 x = 1\} \\ &= -\frac{(1 + \sin x)}{(1 + \sin x)^2} \\ &= \frac{-1}{1 + \sin x} \end{aligned}$$

Since $\frac{-1}{1 + \sin x}$ never equals 0, there are no horizontal tangents.

11 a $y = \sin x \quad \therefore \frac{dy}{dx} = \cos x$

When $x = 0$, $\frac{dy}{dx} = \cos 0 = 1$

$\therefore$ the tangent has equation $\frac{y-0}{x-0} = 1$
or $y = x$

b $y = \tan x \quad \therefore \frac{dy}{dx} = \frac{1}{\cos^2 x}$

When $x = 0$, $\frac{dy}{dx} = \frac{1}{\cos^2 0} = 1$

$\therefore$ the tangent has equation $\frac{y-0}{x-0} = 1$
or $y = x$

c $y = \cos x \quad \therefore \frac{dy}{dx} = -\sin x$

When $x = \frac{\pi}{6}$, $y = \frac{\sqrt{3}}{2}$

and $\frac{dy}{dx} = -\sin\left(\frac{\pi}{6}\right) = -\frac{1}{2}$

So, the normal has gradient 2,

and its equation is $\frac{y - \frac{\sqrt{3}}{2}}{x - \frac{\pi}{6}} = 2$

$$\therefore y - \frac{\sqrt{3}}{2} = 2x - \frac{\pi}{3}$$

$$\therefore 2x - y = \frac{\pi}{3} - \frac{\sqrt{3}}{2}$$

d $y = \frac{1}{\sin(2x)} = (\sin(2x))^{-1}$

$$\begin{aligned} \therefore \frac{dy}{dx} &= -1(\sin(2x))^{-2} \times 2 \cos(2x) \\ &= -\frac{2 \cos(2x)}{(\sin(2x))^2} \end{aligned}$$

When $x = \frac{\pi}{4}$, $y = 1$

and $\frac{dy}{dx} = -\frac{2 \cos(\frac{\pi}{2})}{(\sin(\frac{\pi}{2}))^2} = 0$

$\therefore$ the gradient of the normal is undefined,
so the normal is $x = \frac{\pi}{4}$.

12 a $y = \sec x$

$$\therefore \frac{dy}{dx} = \sec x \tan x$$

When $x = \frac{\pi}{4}$, $y = \sec\left(\frac{\pi}{4}\right) = \sqrt{2}$

$$\text{and } \frac{dy}{dx} = \sec\left(\frac{\pi}{4}\right) \tan\left(\frac{\pi}{4}\right) = \sqrt{2}$$

$\therefore$ the gradient of the tangent at $\left(\frac{\pi}{4}, \sqrt{2}\right)$ is $\sqrt{2}$ and the equation of the tangent is:

$$\frac{y - \sqrt{2}}{x - \frac{\pi}{4}} = \sqrt{2}$$

$$\therefore y - \sqrt{2} = \sqrt{2}x - \frac{\sqrt{2}\pi}{4}$$

$$\begin{aligned} \therefore \sqrt{2}x - y &= \frac{\sqrt{2}\pi}{4} - \sqrt{2} \\ &= \sqrt{2}\left(\frac{\pi}{4} - 1\right) \end{aligned}$$

b $y = \cot\left(\frac{x}{2}\right)$

$$\therefore \frac{dy}{dx} = -\frac{1}{2} \csc^2\left(\frac{x}{2}\right)$$

When $x = \frac{\pi}{3}$, $y = \cot\left(\frac{\pi}{6}\right) = \sqrt{3}$

$$\text{and } \frac{dy}{dx} = -\frac{1}{2} \csc^2\left(\frac{\pi}{6}\right) = -2$$

$\therefore$ the gradient of the tangent at $\left(\frac{\pi}{3}, \sqrt{3}\right)$ is -2 and the equation of the tangent is:

$$\frac{y - \sqrt{3}}{x - \frac{\pi}{3}} = -2$$

$$\therefore y - \sqrt{3} = -2x + \frac{2\pi}{3}$$

$$\therefore 2x + y = \frac{2\pi}{3} + \sqrt{3}$$

13 a $y = \csc x$

$$\therefore \frac{dy}{dx} = -\csc x \cot x$$

When $x = \frac{\pi}{6}$, $y = \csc\left(\frac{\pi}{6}\right)$ and $\frac{dy}{dx} = -\csc\left(\frac{\pi}{6}\right) \cot\left(\frac{\pi}{6}\right)$

$\therefore$ the gradient of the normal at $\left(\frac{\pi}{6}, 2\right)$ is $\frac{1}{2\sqrt{3}}$

$$\therefore \frac{y - 2}{x - \frac{\pi}{6}} = \frac{1}{2\sqrt{3}}$$

$$\therefore 2\sqrt{3}(y - 2) = x - \frac{\pi}{6}$$

$$\therefore 2\sqrt{3}y - 4\sqrt{3} = x - \frac{\pi}{6}$$

$\therefore$ the gradient of the normal at $(\pi, \sqrt{2})$ is $-\sqrt{6}$ and the equation of the normal is:

$$\frac{y - \sqrt{2}}{x - \pi} = -\sqrt{6}$$

$$\therefore y - \sqrt{2} = -\sqrt{6}(x - \pi)$$

$$\therefore y - \sqrt{2} = -\sqrt{6}x + \pi\sqrt{6}$$

- 14 a** Consider the tangent to $y = x^3$ at $x = 2$.
When $x = 2$, $y = 2^3 = 8$ so the point of contact is $(2, 8)$

Now $\frac{dy}{dx} = 3x^2$ and so at $x = 2$,

$$\frac{dy}{dx} = 3(2)^2 = 12$$

$\therefore$ the tangent at $(2, 8)$ has gradient 12 and

$$\text{its equation is } \frac{y - 8}{x - 2} = 12$$

$$\therefore y - 8 = 12x - 24$$

$$\therefore y = 12x - 16$$

$\therefore$ the tangent meets the curve where

$$12x - 16 = x^3$$

$$\therefore x^3 - 12x + 16 = 0$$

Because the tangent touches the curve at $x = 2$, there must be a repeated solution at this point.

$\therefore (x - 2)^2$ must be a factor of this cubic

$$\therefore (x - 2)^2(x + 4) = 0$$

$\therefore$ the tangent meets the curve again when $x = -4$.

When $x = -4$, $y = (-4)^3 = -64$

$\therefore$ the tangent meets the curve again at $(-4, -64)$.

- b** Consider the tangent to $y = -x^3 + 2x^2 + 1$ at $x = -1$.

$$\text{When } x = -1, y = -(-1)^3 + 2(-1)^2 + 1 = 4$$

and so the point of contact is $(-1, 4)$.

Now $\frac{dy}{dx} = -3x^2 + 4x$ and so at $x = -1$,

$$\frac{dy}{dx} = -3(-1)^2 + 4(-1) = -7$$

$\therefore$ the tangent at $(-1, 4)$ has gradient -7 and its equation is

$$\frac{y - 4}{x - (-1)} = -7$$

$$\therefore y - 4 = -7(x + 1)$$

$$\therefore y = -7x - 3$$

$\therefore$ the tangent meets the curve where

$$-7x - 3 = -x^3 + 2x^2 + 1$$

$$\therefore x^3 - 2x^2 - 7x - 4 = 0$$

Because the tangent touches the curve at $x = -1$, there must be a repeated solution at this point.

$\therefore (x + 1)^2$ must be a factor of this cubic

$$\therefore (x + 1)^2(x - 4) = 0$$

$\therefore$ the tangent meets the curve again when $x = 4$.

$$\text{When } x = 4, y = -(4)^3 + 2(4)^2 + 1 = -64 + 32 + 1 = -31$$

$\therefore$ the tangent meets the curve again at $(4, -31)$.

- 15 a** $f(x) = x^2 + \frac{4}{x^2}$
 $\therefore f'(x) = 2x - 2 \times \frac{4}{x^3}$
 $\therefore f'(x) = 2x - \frac{8}{x^3}$

- b** Horizontal tangents have gradient 0, so

$$2x - \frac{8}{x^3} = 0$$

$$\therefore 2x^4 = 8$$

$$\therefore x^4 = 4$$

$$\therefore x = \pm\sqrt{2}$$

- c** When $x = -\sqrt{2}$,
 $f(-\sqrt{2}) = (-\sqrt{2})^2 + \frac{4}{(-\sqrt{2})^2} = 2 + \frac{4}{2} = 4$

$\therefore$ the horizontal tangent at $(-\sqrt{2}, 4)$ is $y = 4$.

When $x = \sqrt{2}$,

$$f(\sqrt{2}) = (\sqrt{2})^2 + \frac{4}{(\sqrt{2})^2} = 2 + \frac{4}{2} = 4$$

$\therefore$ the horizontal tangent at $(\sqrt{2}, 4)$ is $y = 4$.

$\therefore$ the tangents are the same line because they have the same equation.

- 16** $y = x^2e^x$ so when $x = 1$, $y = e$
 $\therefore$ the point of contact is $(1, e)$.

Now $\frac{dy}{dx} = 2xe^x + x^2e^x$

$\therefore$ when $x = 1$, $\frac{dy}{dx} = 2e + e = 3e$

$\therefore$ the tangent has equation $\frac{y - e}{x - 1} = 3e$

$$\therefore y - e = 3ex - 3e$$

$$\therefore y - 3ex = -2e$$

$$\therefore 3ex - y = 2e$$

The tangent cuts the x -axis when

$$y = 0$$

$$\therefore 3ex = 2e$$

$$\therefore x = \frac{2}{3}$$

and the y -axis when

$$x = 0$$

$$\therefore -y = 2e$$

$$\therefore y = -2e$$

So, A is $(\frac{2}{3}, 0)$ and B is $(0, -2e)$.

- 17 a** Consider the tangent to $y = x^2 - x + 9$ at $x = a$.

When $x = a$, $y = a^2 - a + 9$, so the point of contact is $(a, a^2 - a + 9)$.

Now $\frac{dy}{dx} = 2x - 1$ and so at $x = a$, $\frac{dy}{dx} = 2a - 1$

$\therefore$ the gradient of the tangent at $(a, a^2 - a + 9)$ is $2a - 1$

$\therefore$ the equation of the tangent is $\frac{y - (a^2 - a + 9)}{x - a} = 2a - 1$

$$\therefore y - (a^2 - a + 9) = (2a - 1)(x - a)$$

$$\therefore y = (2a - 1)x - 2a^2 + a + a^2 - a + 9$$

$$\therefore y = (2a - 1)x - a^2 + 9 \quad \dots (1)$$

But this tangent passes through $(0, 0)$, so $0 = a^2 - 9$

$$\therefore (a + 3)(a - 3) = 0$$

$$\therefore a = \pm 3$$

$\therefore$ the tangents are: At $a = 3$, $y = (2(3) - 1)x - 3^2 + 9$ {from (1)}

$\therefore y = 5x$, with contact at $(3, 15)$.

At $a = -3$, $y = (2(-3) - 1)x - (-3)^2 + 9$ {from (1)}

$\therefore y = -7x$, with contact at $(-3, 21)$.

- b** Let (a, a^3) lie on $y = x^3$.

Now $\frac{dy}{dx} = 3x^2$, so at $x = a$, $\frac{dy}{dx} = 3a^2$

$\therefore$ the gradient of the tangent at (a, a^3) is $3a^2$

$\therefore$ the equation of the tangent is $\frac{y - a^3}{x - a} = 3a^2$ or $y - a^3 = (3a^2)(x - a)$

But this tangent passes through $(-2, 0)$, so $0 - a^3 = 3a^2(-2 - a)$

$$\therefore -a^3 = -6a^2 - 3a^3$$

$$\therefore 2a^3 + 6a^2 = 0$$

$$\therefore 2a^2(a + 3) = 0$$

$$\therefore a = 0 \text{ or } -3$$

If $a = 0$, the tangent equation is $y = 0$, with contact point $(0, 0)$.

If $a = -3$, the tangent equation is $y - (-27) = 27(x + 3)$

$\therefore y = 27x + 54$, with contact point $(-3, -27)$.

- c** Let $(a, \sqrt{a})$ lie on $y = \sqrt{x}$.

Now $\frac{dy}{dx} = \frac{1}{2}x^{-\frac{1}{2}} = \frac{1}{2\sqrt{x}}$, so at $x = a$, $\frac{dy}{dx} = \frac{1}{2\sqrt{a}}$

$\therefore$ the gradient of the tangent at $(a, \sqrt{a})$ is $\frac{1}{2\sqrt{a}}$

and the gradient of the normal at this point is $-2\sqrt{a}$.

$\therefore$ the normal has equation $\frac{y - \sqrt{a}}{x - a} = -2\sqrt{a}$

$$\text{or } y - \sqrt{a} = -2\sqrt{a}(x - a)$$

But this normal passes through $(4, 0)$, so $0 - \sqrt{a} = -2\sqrt{a}(4 - a)$

$$\therefore 2\sqrt{a}(4 - a) - \sqrt{a} = 0$$

$$\therefore \sqrt{a}(8 - 2a - 1) = 0$$

$$\therefore \sqrt{a}(7 - 2a) = 0$$

$$\therefore a = 0 \text{ or } \frac{7}{2}$$

But $a = 0$ is the endpoint of the function, so there is no normal here.

When $a = \frac{7}{2}$, $y - \sqrt{\frac{7}{2}} = -2\sqrt{\frac{7}{2}}\left(x - \frac{7}{2}\right)$
 $\therefore \sqrt{2}y - \sqrt{7} = -2\sqrt{7}\left(x - \frac{7}{2}\right)$
 $\therefore \sqrt{2}y + 2\sqrt{7}x = 7\sqrt{7} + \sqrt{7}$
 $\therefore \sqrt{2}y + 2\sqrt{7}x = 8\sqrt{7}$
 $\therefore y = -\sqrt{14}x + 4\sqrt{14}$ with contact point $\left(\frac{7}{2}, \sqrt{\frac{7}{2}}\right)$.

18 $y = e^x$ so when $x = a$, $y = e^a$
 $\therefore$ the point of contact is (a, e^a) .
Now $\frac{dy}{dx} = e^x$
 $\therefore$ at the point (a, e^a) , $\frac{dy}{dx} = e^a$
 $\therefore$ the tangent has equation $\frac{y - e^a}{x - a} = e^a$
or $y - e^a = e^a(x - a) \dots (*)$
 $\therefore y = e^a x + e^a - ae^a$

Since the tangent passes through the origin,
 $(0, 0)$ must satisfy $(*)$
 $\therefore 0 - e^a = e^a(0 - a)$
 $\therefore -e^a = -ae^a$
 $\therefore e^a(a - 1) = 0$
 $\therefore a = 1$ {as $e^a > 0$ }
So the equation of the tangent is
 $y - e = ex - e$ or $y = ex$.

b Let $\left(a, \frac{8}{a^2}\right)$ lie on $f(x) = \frac{8}{x^2} = 8x^{-2}$
Now $f'(x) = -16x^{-3} = -\frac{16}{x^3}$
 $\therefore f'(a) = -\frac{16}{a^3}$
 $\therefore$ the gradient of the tangent at $\left(a, \frac{8}{a^2}\right)$ is $-\frac{16}{a^3}$
 $\therefore$ the equation of the tangent is $\frac{y - \frac{8}{a^2}}{x - a} = -\frac{16}{a^3}$
 $\therefore a^3y - 8a = -16x + 16a$
 $\therefore 16x + a^3y = 24a$

c The tangent cuts the x -axis when $y = 0$
 $\therefore 16x = 24a$
 $\therefore x = \frac{3}{2}a$
 $\therefore$ A is $\left(\frac{3}{2}a, 0\right)$.
The tangent cuts the y -axis when $x = 0$
 $\therefore a^3y = 24a$
 $\therefore y = \frac{24}{a^2}$
 $\therefore$ B is $\left(0, \frac{24}{a^2}\right)$.

d Area of triangle OAB
 $= \left| \frac{1}{2} \times \left(\frac{3}{2}a\right) \times \left(\frac{24}{a^2}\right) \right|$
 $= \frac{18}{|a|} \text{ units}^2$
As $a \rightarrow \infty$, $\frac{18}{a} \rightarrow 0$
 $\therefore \text{area} \rightarrow 0$

20 $y_1 = \sqrt{x + a}$ and $y_2 = \sqrt{2x - x^2}$
 $\therefore \frac{dy_1}{dx} = \frac{1}{2}(x + a)^{-\frac{1}{2}}$

 $\therefore \frac{dy_2}{dx} = \frac{1}{2}(2x - x^2)^{-\frac{1}{2}}(2 - 2x)$
 $= \frac{1 - x}{\sqrt{2x - x^2}}$
 y_1 intersects y_2 when $y_1 = y_2$
 $\therefore \sqrt{x + a} = \sqrt{2x - x^2}$
 $\therefore x + a = 2x - x^2 \dots (1)$

$$\therefore \frac{-2b}{(x+1)^3} = -\frac{3}{4}$$

$$\therefore b = \frac{3(x+1)^3}{8} \quad \dots (2)$$

$$\therefore x = 1$$

$$\therefore b = \frac{3(1+1)^3}{8}$$

$$= \frac{3 \times 2^3}{8}$$

$$= 3$$

22 $y = 3e^{-x}$ and $y = 2 + e^x$ meet when $3e^{-x} = 2 + e^x$

$$\therefore 3 = 2e^x + e^{2x} \quad \{\times e^x\}$$

$$\therefore e^{2x} + 2e^x - 3 = 0$$

$$\therefore (e^x + 3)(e^x - 1) = 0$$

$$\therefore e^x = -3 \text{ or } 1$$

$$\therefore e^x = 1 \text{ and so } x = 0 \quad \{\text{as } e^x > 0\}$$

Now when $x = 0$, $y = 3e^0 = 3$, so the graphs meet at $(0, 3)$.

For $y = 2 + e^x$, $\frac{dy}{dx} = e^x$,

so at the point $(0, 3)$, $\frac{dy}{dx} = e^0 = 1$

$\therefore$ the gradient of the tangent at this point is 1

$\therefore$ the tangent has direction vector $\begin{pmatrix} 1 \\ 1 \end{pmatrix}$

If θ is the acute angle between the tangents, then

$$\cos \theta = \frac{|1(1) + 1(-3)|}{\sqrt{1^2 + 1^2} \sqrt{1^2 + (-3)^2}} = \frac{|-2|}{\sqrt{2}\sqrt{10}} = \frac{2}{\sqrt{20}} = \frac{1}{\sqrt{5}}$$

$$\therefore \theta \approx 63.43^\circ$$

For $y = 3e^{-x}$, $\frac{dy}{dx} = -3e^{-x}$,

so at the point $(0, 3)$, $\frac{dy}{dx} = -3$

$\therefore$ the gradient of the tangent at this point is -3

$\therefore$ the tangent has direction vector $\begin{pmatrix} 1 \\ -3 \end{pmatrix}$

23 a $y = ax^2$, $a > 0$ touches $y = \ln x$ when $ax^2 = \ln x$

If the curves touch when $x = b$ then $ab^2 = \ln b$ (1)

Now for $y = ax^2$, $\frac{dy}{dx} = 2ax$ and for $y = \ln x$, $\frac{dy}{dx} = \frac{1}{x}$

$\therefore$ when $x = b$, $\frac{dy}{dx} = 2ab$ $\therefore$ when $x = b$, $\frac{dy}{dx} = \frac{1}{b}$

Since the curves touch each other, they share a common tangent. $\therefore 2ab = \frac{1}{b}$ (2)

b Now $ab^2 = \frac{1}{2}$ {from (2)}

and $ab^2 = \ln b$ {from (1)}

$$\therefore \ln b = \frac{1}{2}$$

$$\therefore b = e^{\frac{1}{2}} = \sqrt{e}$$

$$\text{When } x = b = \sqrt{e}, y = \ln x = \ln e^{\frac{1}{2}} = \frac{1}{2}$$

$\therefore$ the point of contact is $(\sqrt{e}, \frac{1}{2})$.

d The tangent has gradient $\frac{1}{b} = \frac{1}{\sqrt{e}}$ and passes through $(\sqrt{e}, \frac{1}{2})$

$$\therefore \text{the tangent is } \frac{y - \frac{1}{2}}{x - \sqrt{e}} = \frac{1}{\sqrt{e}} \therefore y - \frac{1}{2} = \frac{1}{\sqrt{e}}(x - \sqrt{e})$$

$$\therefore y - \frac{1}{2} = \frac{1}{\sqrt{e}}x - 1$$

$$\therefore y = e^{-\frac{1}{2}}x - \frac{1}{2}$$

c $a = \frac{1}{2b^2}$ {from (2)}

$$\therefore a = \frac{1}{2(\sqrt{e})^2} = \frac{1}{2e}$$

24 a $x^2 + y^2 = 1$

$$\therefore y^2 = 1 - x^2$$

$$\therefore y = \pm \sqrt{1 - x^2} \\ = \pm (1 - x^2)^{\frac{1}{2}}$$

$$\text{When } x = \frac{1}{2}, \text{ then } y = \pm \sqrt{1 - (\frac{1}{2})^2}$$

$$= \pm \sqrt{1 - \frac{1}{4}}$$

$$= \pm \sqrt{\frac{3}{4}}$$

$$= \pm \frac{\sqrt{3}}{2}$$

So we need to find the tangents at $(\frac{1}{2}, \frac{\sqrt{3}}{2})$ and $(\frac{1}{2}, -\frac{\sqrt{3}}{2})$.

$$\begin{aligned}\text{Now } \frac{dy}{dx} &= \pm \frac{1}{2}(1-x^2)^{-\frac{1}{2}}(-2x) \\ &= \frac{-x}{\pm \sqrt{1-x^2}} \\ &= \mp \frac{x}{\sqrt{1-x^2}}\end{aligned}$$

$$\text{When } x = \frac{1}{2}, \text{ then } \frac{dy}{dx} = \mp \frac{\frac{1}{2}}{\sqrt{1-(\frac{1}{2})^2}} = \mp \frac{\frac{1}{2}}{\sqrt{\frac{3}{4}}} = \mp \frac{1}{2} \times \frac{2}{\sqrt{3}} = \mp \frac{1}{\sqrt{3}}$$

$\therefore$ the gradient of the tangent at $(\frac{1}{2}, \frac{\sqrt{3}}{2})$ is $-\frac{1}{\sqrt{3}}$

and the gradient of the tangent at $(\frac{1}{2}, -\frac{\sqrt{3}}{2})$ is $\frac{1}{\sqrt{3}}$

$$\therefore \text{ the equation of the tangent at } (\frac{1}{2}, \frac{\sqrt{3}}{2}) \text{ is } \frac{y - \frac{\sqrt{3}}{2}}{x - \frac{1}{2}} = -\frac{1}{\sqrt{3}}$$

$$\therefore \sqrt{3}(y - \frac{\sqrt{3}}{2}) = -(x - \frac{1}{2})$$

$$\therefore \sqrt{3}y - \frac{3}{2} = -x + \frac{1}{2}$$

$$\therefore x + \sqrt{3}y = 2$$

$$\text{and the equation of the tangent at } (\frac{1}{2}, -\frac{\sqrt{3}}{2}) \text{ is } \frac{y - (-\frac{\sqrt{3}}{2})}{x - \frac{1}{2}} = \frac{1}{\sqrt{3}}$$

$$\therefore \sqrt{3}(y + \frac{\sqrt{3}}{2}) = x - \frac{1}{2}$$

$$\therefore \sqrt{3}y + \frac{3}{2} = x - \frac{1}{2}$$

$$\therefore x - \sqrt{3}y = 2$$

b On the x -axis $y = 0$, $\therefore x = 2$.

So, the tangents intersect on the x -axis at $(2, 0)$.

with sign

5 $f(x) = 2x^3 + ax^2 - 24x + 1$

$$\therefore f'(x) = 6x^2 + 2ax - 24$$

But $f'(-2) = 0$

$$\therefore 3(-2)^2 + a = 0$$

$$\therefore 12 + a = 0$$

$$\therefore a = -12$$

Also, $f(-2) = 3$

$$\therefore (-2)^3 - 12(-2) + b = 3$$

$$\therefore -8 + 24 + b = 3$$

$$\therefore b = -13$$

b $f'(x) = \ln x + \frac{x}{x} \quad \{\text{product rule}\}$

$$= \ln x + 1$$

which is 0 when $\ln x = -1$

$$\therefore x = e^{-1} = \frac{1}{e}$$

So, there is a local minimum at $\left(\frac{1}{e}, \frac{1}{e} \ln \frac{1}{e}\right)$

$\therefore$ the global minimum value of $f(x)$ is $\frac{1}{e} \ln e^{-1} = -\frac{1}{e}$

- d** If $f(x) = e^{\sin x}$ then $f'(x) = e^{\sin x} \times \cos x$
 $\therefore f'(x) = 0$ when $\cos x e^{\sin x} = 0$
 $\therefore \cos x = 0$ $\{e^{\sin x} > 0 \text{ for all } x\}$
 $\therefore x = \frac{\pi}{2} + k\pi$, k an integer

On the domain $0 \leq x \leq 2\pi$, $f'(x) = 0$
 when $x = \frac{\pi}{2}, \frac{3\pi}{2}$.

Sign diagram for $f'(x)$ is:

There is a local maximum at $(\frac{\pi}{2}, e)$
 and a local minimum at $(\frac{3\pi}{2}, \frac{1}{e})$.

e If $f(x) = \sin(2x) + 2\cos x$ then $f'(x) = 2\cos(2x) - 2\sin x$
 $\therefore f'(x) = 0$ when $2\cos(2x) - 2\sin x = 0$
 $\therefore 2(1 - 2\sin^2 x) - 2\sin x = 0$
 $\therefore -2(2\sin^2 x + \sin x - 1) = 0$
 $\therefore -2(2\sin x - 1)(\sin x + 1) = 0$

$\therefore$ when $\sin x = \frac{1}{2}$ or $\sin x = -1$
On the domain $0 \leq x \leq 2\pi$, when $x = \frac{\pi}{6}, \frac{5\pi}{6}, \frac{3\pi}{2}$.

$\therefore$ there is a local maximum at $\left(\frac{\pi}{6}, \frac{3\sqrt{3}}{2}\right)$,
a local minimum at $\left(\frac{5\pi}{6}, -\frac{3\sqrt{3}}{2}\right)$
and a stationary point of inflection at $\left(\frac{3\pi}{2}, 0\right)$.

9 Let the cubic polynomial be

$$\begin{aligned} P(x) &= ax^3 + bx^2 + cx + d \\ \therefore P'(x) &= 3ax^2 + 2bx + c \quad \dots (1) \end{aligned}$$

Now $(0, 2)$ lies on $P(x)$, so $P(0) = 2$
 $\therefore a(0) + b(0) + c(0) + d = 2$
 $\therefore d = 2$

The tangent at $(0, 2)$ is $y = 9x + 2$, so
 $P'(0) = 9$
 $\therefore 3a(0) + 2b(0) + c = 9$
 $\therefore c = 9 \quad \dots (2)$

There is a stationary point at $(-1, -7)$, so
 $P'(-1) = 0$

$$\begin{aligned} \therefore 3a(-1)^2 + 2b(-1) + c &= 0 \quad \{\text{using (1)}\} \\ \therefore 3a - 2b + c &= 0 \\ \text{So, using (2), } 3a - 2b &= -9 \quad \dots (3) \end{aligned}$$

Finally, $(-1, -7)$ lies on $P(x)$
 $\therefore a(-1)^3 + b(-1)^2 + c(-1) + d = -7$
 $\therefore -a + b - 9 + 2 = -7$
 $\therefore b - a = 0$
 $\therefore a = b$

$$\begin{aligned} \text{So, using (3), } 3a - 2a &= -9 \\ \therefore a &= -9 \\ \therefore a &= b = -9 \\ \therefore P(x) &= -9x^3 - 9x^2 + 9x + 2 \end{aligned}$$

10 a $f(x) = x^3 - 12x - 2$, for $-3 \leq x \leq 5$
 $\therefore f'(x) = 3x^2 - 12$
 $= 3(x + 2)(x - 2)$
which is 0 when $x = -2$ or 2

x	-3	-2	2	5
$f(x)$	7	14	-18	63

$\therefore$ the greatest value is 63 when $x = 5$, and the least value is -18 when $x = 2$.

b $f(x) = 4 - 3x^2 + x^3$, for $-2 \leq x \leq 3$
 $\therefore f'(x) = -6x + 3x^2$
 $= 3x(x - 2)$
which is 0 when $x = 0$ or 2

x	-2	0	2	3
$f(x)$	-16	4	0	4

$\therefore$ greatest value is 4 when $x = 0$ or $x = 3$, least value is -16 when $x = -2$.

11 $y = 4e^{-x} \sin x$

$$\therefore \frac{dy}{dx} = -4e^{-x} \sin x + 4e^{-x} \cos x$$

$$\therefore \text{stationary points occur when } -4e^{-x} \sin x + 4e^{-x} \cos x = 0$$

$$\therefore 4e^{-x}(\cos x - \sin x) = 0$$

$$\therefore \cos x - \sin x = 0 \quad \{e^{-x} > 0 \text{ for all } x\}$$

$$\therefore \sin x = \cos x$$

$$\therefore \tan x = 1$$

$$\therefore x = \frac{\pi}{4} + k\pi, \quad k \text{ an integer}$$

Sign diagram of $\frac{dy}{dx}$ is:

$$\therefore y = 4e^{-x} \sin x \text{ has a local maximum when } x = \frac{\pi}{4}.$$

12 $f(t) = ate^{bt^2}$

$$\therefore f'(t) = ae^{bt^2} + at \times 2bte^{bt^2}$$

$$= ae^{bt^2}(1 + 2bt^2)$$

There is a maximum of 1 when $t = 2$

$$\therefore f'(2) = 0 \text{ and } ae^{b2^2}(1 + 2b2^2) = 0$$

$$\therefore ae^{4b}(1 + 8b) = 0 \quad \dots (1)$$

Also the point $(2, 1)$ lies on $f(t)$

$$\therefore f(2) = a2e^{b2^2} = 1$$

$$\therefore ae^{4b} = \frac{1}{2} \quad \dots (2)$$

$$\text{Substituting this into (1)} \quad \therefore \frac{1}{2}(1 + 8b) = 0$$

$$\therefore 1 + 8b = 0$$

$$\therefore b = -\frac{1}{8}$$

$$\text{Substituting this into (2)} \quad \therefore ae^{4(-\frac{1}{8})} = \frac{1}{2}$$

$$\therefore ae^{-\frac{1}{2}} = \frac{1}{2}$$

$$\therefore a = \frac{1}{2}e^{\frac{1}{2}} = \frac{\sqrt{e}}{2}$$

13 Consider $f(x) = \frac{\ln x}{x}$

$$\therefore f'(x) = \frac{\left(\frac{1}{x}\right)x - \ln x(1)}{x^2} = \frac{1 - \ln x}{x^2}$$

$$\therefore f'(x) = 0 \text{ when } 1 - \ln x = 0$$

$$\therefore \ln x = 1$$

$$\therefore x = e$$

Sign diagram of $f'(x)$ is:

$$\text{Now } f(e) = \frac{\ln e}{e} = \frac{1}{e}$$

$$\therefore \text{there is a local maximum at } \left(e, \frac{1}{e}\right)$$

$$\therefore f(x) \leq \frac{1}{e} \text{ for all } x, \text{ and so } \frac{\ln x}{x} \leq \frac{1}{e} \text{ for all } x > 0$$

14

a

$f(x) = x - \ln x$
 $\therefore f'(x) = 1 - \frac{1}{x} = \frac{x-1}{x}$ and the sign diagram of $f'(x)$ is:

$\therefore f(x)$ has a local minimum at $(1, 1 - \ln 1)$ or $(1, 1)$. This is the only turning point.

b

$f(x) \geq 1$ for all $x > 0$
 $\therefore x - \ln x \geq 1$
 $\therefore \ln x \leq x - 1$ for all $x > 0$

15

a

$f(x) = \sec x = \frac{1}{\cos x}$
 $\therefore f(x)$ is undefined when $\cos x = 0$.
But $\cos x = 0$ when $x = \frac{\pi}{2} + k\pi, k \in \mathbb{Z}$
 $\therefore$ for $0 \leq x \leq 2\pi$, $f(x)$ is undefined when $x = \frac{\pi}{2}$ or $\frac{3\pi}{2}$.

b

$f'(x) = \sec x \tan x$
 $= \frac{1}{\cos x} \times \frac{\sin x}{\cos x}$
 $f'(x) = 0$ when $\sin x = 0$
 $\therefore f'(x) = 0$ when $x = 0 + k\pi, k \in \mathbb{Z}$
 $\therefore$ for $0 \leq x \leq 2\pi$, $x = 0, \pi, 2\pi$
 $\therefore$ sign diagram of $f'(x)$ is:

$f(0) = \sec 0 = 1$
 $f(\pi) = \sec \pi = -1$
 $f(2\pi) = \sec 2\pi = 1$
 $\therefore$ there is a local maximum at $(\pi, -1)$ and local minima at $(0, 1)$ and $(2\pi, 1)$.

c

$f(x) = \sec x$
 $\therefore f(x + 2\pi) = \sec(x + 2\pi)$
 $= \frac{1}{\cos(x + 2\pi)}$
 $= \frac{1}{\cos x \cos 2\pi - \sin x \sin 2\pi}$
 $= \frac{1}{\cos x \times 1 - \sin x \times 0}$
 $= \frac{1}{\cos x}$
 $= \sec x$
 $= f(x), x \in \mathbb{R}$
 $\therefore$ the graph has a period of 2π .

a

Point	$f(x)$	$f'(x)$	$f''(x)$
A	+	-	+
B	-	0	+
C	+	+	0
D	+	0	-
E	0	-	-

b

The turning points of $y = f(x)$ are point B, a local minimum, and point D, a local maximum.

c

The inflection point of $y = f(x)$ is point C, a non-stationary point of inflection.

- 2 a** $f(x) = x^2 + 3$
 $\therefore f'(x) = 2x$
 $\therefore f''(x) = 2$
 Since $f''(x) \neq 0$,
 no points of inflection exist.

- b** $f(x) = 2 - x^3$
 $\therefore f'(x) = -3x^2$ 
 $\therefore f''(x) = -6x$ 

Now $f''(x) = 0$ when $x = 0$,
 and $f'(0) = 0$
 $\therefore$ there is a stationary inflection at $(0, 2)$.

- c** $f(x) = x^3 - 6x^2 + 9x + 1$
 $\therefore f'(x) = 3x^2 - 12x + 9$
 $= 3(x^2 - 4x + 3)$
 $= 3(x - 3)(x - 1)$

and $f''(x) = 6x - 12 = 6(x - 2)$

Now $f''(x) = 0$ when $x = 2$
 and $f'(2) \neq 0$
 $\therefore$ there is a non-stationary inflection at $(2, f(2))$ which is $(2, 3)$.

- e** $f(x) = 3 - \frac{1}{\sqrt{x}} = 3 - x^{-\frac{1}{2}}$
 $\therefore f'(x) = \frac{1}{2}x^{-\frac{3}{2}}$
 and $f''(x) = -\frac{3}{4}x^{-\frac{5}{2}} = \frac{-3}{4x^2\sqrt{x}}$

Now $f''(x) \neq 0$ for all x
 $\therefore$ there are no points of inflection.

- d** $f(x) = -3x^4 - 8x^3 + 2$
 $\therefore f'(x) = -12x^3 - 24x^2$
 $= -12x^2(x + 2)$

and $f''(x) = -36x^2 - 48x$
 $= -12x(3x + 4)$

$\therefore$ there is a stationary inflection at $(0, 2)$,
 and a non-stationary inflection at $(-\frac{4}{3}, f(-\frac{4}{3}))$, which is $(-\frac{4}{3}, \frac{310}{27})$.

- f** $f(x) = x^3 + 6x^2 + 12x + 5$
 $\therefore f'(x) = 3x^2 + 12x + 12$
 $= 3(x^2 + 4x + 4)$
 $= 3(x + 2)^2$

and $f''(x) = 6x + 12 = 6(x + 2)$

Now $f''(x) = 0$ when $x = -2$
 and $f'(-2) = 0$
 $\therefore$ there is a stationary inflection at $(-2, f(-2))$ which is $(-2, -3)$.

- 3 a** $f(x) = x^2$
 $\therefore f'(x) = 2x$ which has sign diagram:
 and $f''(x) = 2$

- i** There is a local minimum at $(0, 0)$.
- ii** There are no points of inflection as $f''(x) \neq 0$.
- iii** $f(x)$ is increasing when $x \geq 0$, and decreasing when $x \leq 0$.
- iv** $f(x)$ is concave up for all x as $f''(x) > 0$ for all x .

b $f(x) = x^3$
 $\therefore f'(x) = 3x^2$ which has sign diagram:

and $f''(x) = 6x$ which has sign diagram:

- i** A stationary inflection at $(0, 0)$.
- ii** A stationary inflection at $(0, 0)$.
- iii** $f(x)$ is increasing for all real x .
- iv** $f(x)$ is concave up when $x \geq 0$, and concave down when $x \leq 0$.

c $f(x) = \sqrt{x}$

$\therefore f'(x) = \frac{1}{2}x^{-\frac{1}{2}} = \frac{1}{2\sqrt{x}}$ which has sign diagram:

and $f''(x) = -\frac{1}{4}x^{-\frac{3}{2}} = \frac{-1}{4x\sqrt{x}}$ which has sign diagram:

- i** There are no stationary points as $f'(x) \neq 0$.
- ii** There are no points of inflection as $f''(x) \neq 0$.
- iii** $f(x)$ is increasing for all $x \geq 0$, never decreasing.
- iv** $f(x)$ is concave down for all $x \geq 0$ as $f''(x) < 0$ for all $x > 0$, never concave up.

d $f(x) = x^3 - 3x^2 - 24x + 1$

$\therefore f'(x) = 3x^2 - 6x - 24$
 $= 3(x^2 - 2x - 8)$
 $= 3(x - 4)(x + 2)$ which has sign diagram:

and $f''(x) = 6x - 6$
 $= 6(x - 1)$ which has sign diagram:

- i** $f(-2) = 29$, $f(4) = -79$, so there is a local maximum at $(-2, 29)$, and a local minimum at $(4, -79)$.
- ii** $f(1) = -25$, so there is a non-stationary inflection at $(1, -25)$.
- iii** $f(x)$ is increasing for $x \leq -2$ and $x \geq 4$, and decreasing for $-2 \leq x \leq 4$.
- iv** $f(x)$ is concave down for $x \leq 1$, and concave up for $x \geq 1$.

e $f(x) = 3x^4 + 4x^3 - 2$

$\therefore f'(x) = 12x^3 + 12x^2$
 $= 12x^2(x + 1)$ which has sign diagram:

and $f''(x) = 36x^2 + 24x$

$= 12x(3x + 2)$ which has sign diagram:

- i** There is a local minimum at $(-1, f(-1))$ which is $(-1, -3)$, and a stationary inflection at $(0, -2)$.
- ii** There is a non-stationary inflection at $(-\frac{2}{3}, f(-\frac{2}{3}))$ which is $(-\frac{2}{3}, -\frac{70}{27})$, and a stationary inflection at $(0, -2)$.
- iii** $f(x)$ is increasing for $x \geq -1$, and decreasing for $x \leq -1$.
- iv** $f(x)$ is concave down for $-\frac{2}{3} \leq x \leq 0$, and concave up for $x \leq -\frac{2}{3}$ and $x \geq 0$.

f $f(x) = (x - 1)^4$
 $\therefore f'(x) = 4(x - 1)^3$ which has sign diagram:

and $f''(x) = 12(x - 1)^2$ which has sign diagram:

- i** There is a local minimum at $(1, 0)$.
- ii** Since there is no sign change in $f''(x)$ at $x = 1$, there are no points of inflection.
- iii** $f(x)$ is increasing for $x \geq 1$, and decreasing for $x \leq 1$.
- iv** $f(x)$ is concave up for all x .

g $f(x) = x^4 - 4x^2 + 3$
 $f'(x) = 4x^3 - 8x$
 $= 4x(x^2 - 2)$
 $= 4x(x + \sqrt{2})(x - \sqrt{2})$ which has sign diagram:
 $f''(x) = 12x^2 - 8 = 4(3x^2 - 2)$
 $= 4(\sqrt{3}x + \sqrt{2})(\sqrt{3}x - \sqrt{2})$ which has sign diagram:

- i** There is a local maximum at $(0, 3)$, and $f(-\sqrt{2}) = f(\sqrt{2}) = -1$, so there are local minima at $(\sqrt{2}, -1)$ and $(-\sqrt{2}, -1)$.
- ii** $f\left(\sqrt{\frac{2}{3}}\right) = f\left(-\sqrt{\frac{2}{3}}\right) = \frac{7}{9}$, so there are non-stationary inflections at $(\sqrt{\frac{2}{3}}, \frac{7}{9})$ and $(-\sqrt{\frac{2}{3}}, \frac{7}{9})$.
- iii** $f(x)$ is increasing for $-\sqrt{2} \leq x \leq 0$ and $x \geq \sqrt{2}$, and decreasing for $x \leq -\sqrt{2}$ and $0 \leq x \leq \sqrt{2}$.
- iv** $f(x)$ is concave down for $-\sqrt{\frac{2}{3}} \leq x \leq \sqrt{\frac{2}{3}}$, and concave up for $x \leq -\sqrt{\frac{2}{3}}$ and $x \geq \sqrt{\frac{2}{3}}$.

h $f(x) = 3 - \frac{4}{\sqrt{x}} = 3 - 4x^{-\frac{1}{2}}, \quad x > 0$

$\therefore f'(x) = 2x^{-\frac{3}{2}} = \frac{2}{x\sqrt{x}}$ with sign diagram:

and $f''(x) = -3x^{-\frac{5}{2}} = -\frac{3}{x^2\sqrt{x}}$ with sign diagram:

- i** There are no stationary points as $f'(x) \neq 0$.
- ii** There are no points of inflection as $f''(x) \neq 0$.
- iii** $f(x)$ is increasing for all $x > 0$ and never decreasing.
- iv** $f(x)$ is concave down for all $x > 0$ and never concave up.

4 a Consider $f(x) = e^{2x} - 3$

$f(x)$ cuts the x -axis at A when $f(x) = 0$
 $\therefore e^{2x} - 3 = 0$
 $\therefore e^{2x} = 3$
 $\therefore 2x = \ln 3$
 $\therefore x = \frac{\ln 3}{2}$
 $\therefore$ A is $(\frac{\ln 3}{2}, 0)$

$f(x)$ cuts the y -axis at B when $x = 0$
 $\therefore f(0) = e^{2 \times 0} - 3$
 $= e^0 - 3$
 $= -2$
 $\therefore$ B is $(0, -2)$

b $f(x) = e^{2x} - 3$

$\therefore f'(x) = 2e^{2x}$

Since $e^{2x} > 0$ for all x , $f'(x) > 0$ for all x , and hence $f(x)$ is increasing for all x .

c $f''(x) = 4e^{2x}$, which is always > 0 .

$\therefore f(x)$ is concave up for all x .

e As $x \rightarrow -\infty$, $e^{2x} \rightarrow 0$, so $e^{2x} - 3 \rightarrow -3^+$
 $\therefore y = -3$ is a horizontal asymptote.

5 a The x -intercepts occur when $y = 0$

For $f(x) = e^x - 3$, $e^x - 3 = 0$
 $\therefore e^x = 3$
 $\therefore x = \ln 3$

and for $g(x) = 3 - \frac{5}{e^x}$, $3 - \frac{5}{e^x} = 0$
 $\therefore \frac{3e^x - 5}{e^x} = 0$

$\therefore f(x)$ has x -intercept $\ln 3$
and $g(x)$ has x -intercept $\ln(\frac{5}{3})$.

$\therefore 3e^x - 5 = 0$
 $\therefore e^x = \frac{5}{3}$
 $\therefore x = \ln(\frac{5}{3})$

The y -intercepts occur when $x = 0$

Now $f(0) = e^0 - 3 = -2$ and $g(0) = 3 - \frac{5}{e^0} = 3 - 5 = -2$

$\therefore$ both $f(x)$ and $g(x)$ have y -intercept -2 .

b As $x \rightarrow \infty$, $f(x) \rightarrow \infty$ As $x \rightarrow \infty$, $g(x) \rightarrow 3^-$
 $x \rightarrow -\infty$, $f(x) \rightarrow -3^+$ $x \rightarrow -\infty$, $g(x) \rightarrow -\infty$

c $f(x)$ and $g(x)$ meet when

$$\begin{aligned} e^x - 3 &= 3 - 5e^{-x} \\ \therefore e^{2x} - 3e^x &= 3e^x - 5 \quad \{ \times e^x \} \\ \therefore e^{2x} - 6e^x + 5 &= 0 \\ \therefore (e^x - 5)(e^x - 1) &= 0 \\ \therefore e^x &= 5 \text{ or } 1 \\ \therefore x &= \ln 5 \text{ or } 0 \end{aligned}$$

$$\text{Now } f(\ln 5) = e^{\ln 5} - 3 = 5 - 3 = 2$$

$$\text{and } f(0) = -2$$

$\therefore f(x)$ and $g(x)$ meet at $(\ln 5, 2)$ and $(0, -2)$.

6 a Consider $y = e^x - 3e^{-x}$

It cuts the x -axis at P when $y = 0$

$$\begin{aligned} \therefore e^x - 3e^{-x} &= 0 \\ \therefore e^{2x} - 3 &= 0 \quad \{ \times e^x \} \\ \therefore e^{2x} &= 3 \\ \therefore 2x &= \ln 3 \\ \therefore x &= \frac{1}{2} \ln 3 \end{aligned}$$

It cuts the y -axis at Q when $x = 0$

$$\begin{aligned} \therefore y &= e^0 - 3e^0 \\ &= 1 - 3 \\ &= -2 \end{aligned}$$

$\therefore$ P is $(\frac{1}{2} \ln 3, 0)$ and Q is $(0, -2)$.

b $\frac{dy}{dx} = e^x + 3e^{-x}$
 $= e^x + \frac{3}{e^x}$

Since $e^x > 0$ for all x ,

$$\frac{dy}{dx} > 0 \text{ for all } x$$

$\therefore$ the function is increasing for all x

c $\frac{dy}{dx} = e^x + 3e^{-x}$
 $\therefore \frac{d^2y}{dx^2} = e^x - 3e^{-x}$
 $= y$

Above the x -axis $y > 0 \therefore \frac{d^2y}{dx^2} > 0$

$\therefore$ the function is concave up

Below the x -axis $y < 0 \therefore \frac{d^2y}{dx^2} < 0$

$\therefore$ the function is concave down

$\therefore$ a non-stationary inflection occurs when $y = 0$

7 $f(x) = \ln(2x - 1) - 3$

a $f(x) = 0$ when $\ln(2x - 1) = 3$

$$\therefore 2x - 1 = e^3$$

$$\therefore 2x = e^3 + 1$$

$$\therefore x = \frac{e^3 + 1}{2} \approx 10.5 \quad \therefore \text{the } x\text{-intercept is } \frac{e^3 + 1}{2}$$

b $f(0)$ cannot be found as $\ln(-1)$ is not defined. $\therefore$ there is no y -intercept.

c $f'(x) = \frac{2}{2x - 1} \therefore f'(1) = \frac{2}{2 - 1} = 2 \therefore$ gradient of tangent $= 2$

d $\ln(2x - 1)$ has meaning provided $2x - 1 > 0 \therefore 2x > 1$ and so $x > \frac{1}{2}$
 $\therefore$ the domain of f is $\{x \mid x > \frac{1}{2}\}$

e $f'(x) = 2(2x - 1)^{-1}$
 $\therefore f''(x) = -2(2x - 1)^{-2}(2)$
 $= \frac{-4}{(2x - 1)^2}, \quad x > \frac{1}{2}$
 $\therefore$ provided $x > \frac{1}{2}$, $f''(x) < 0$
 $\therefore f(x)$ is concave down for all x in the domain of f .

8 a $f(x) = \ln x$ is defined for all $x > 0$.
b $f'(x) = \frac{1}{x}$ which is > 0 for all $x > 0$
 $\therefore f(x)$ is increasing on $x > 0$; its gradient is always positive.
 $f''(x) = -x^{-2} = \frac{-1}{x^2}$ which is < 0 for all $x > 0$ $\therefore f(x)$ is concave down on $x > 0$.

At $y = 1$, $1 = \ln x$
 $\therefore x = e^1 = e$
 $\therefore$ the point of contact is $(e, 1)$
Now $\frac{dy}{dx} = \frac{1}{x}$
 $\therefore$ at $(e, 1)$, $\frac{dy}{dx} = \frac{1}{e}$

$\therefore$ the gradient of the tangent is $\frac{1}{e}$, and the gradient of the normal is $-e$
 $\therefore$ the equation of the normal is $\frac{y - 1}{x - e} = -e$ $\therefore y - 1 = -e(x - e)$
 $\therefore y - 1 = -ex + e^2$
 $\therefore y = -ex + 1 + e^2$

9 Consider $f(x) = \frac{e^x}{x}$.
a $e^x \neq 0$ for all x , so $f(x) \neq 0$ and there is no x -intercept.
 $f(0) = \frac{e^0}{0}$ is undefined, so there is also no y -intercept.

b As $x \rightarrow +\infty$ $f(x) \rightarrow \infty$, and as $x \rightarrow -\infty$, $f(x) \rightarrow 0^-$
(As $x \rightarrow 0^+$, $y \rightarrow +\infty$, and as $x \rightarrow 0^-$, $y \rightarrow -\infty$)
 $\therefore x = 0$ is a vertical asymptote.

c Using the quotient rule, $f'(x) = \frac{e^x x - e^x(1)}{x^2} = \frac{e^x(x - 1)}{x^2}$

with sign diagram:

$f(1) = \frac{e^1}{1} = e$, so there is a local minimum at $(1, e)$.

d Using the product and quotient rules,
 $f''(x) = \frac{[e^x(x - 1) + e^x]x^2 - e^x(x - 1)2x}{x^4}$
 $= \frac{x^3 e^x - \cancel{x^2 e^x} + \cancel{x^2 e^x} - 2x^2 e^x + 2x e^x}{x^4}$
 $= \frac{e^x(x^2 - 2x + 2)}{x^3}$ with sign diagram:

i $f(x)$ is concave up for $x > 0$. **ii** $f(x)$ is concave down for $x < 0$.

f Now $f'(x) = \frac{e^x(x-1)}{x^2}$

$$\therefore f'(-1) = \frac{e^{-1}(-1-1)}{(-1)^2} = -\frac{2}{e}$$

$\therefore$ the gradient of the tangent is $= -\frac{2}{e}$

When $x = -1$, $y = \frac{e^{-1}}{-1} = -\frac{1}{e}$

$\therefore$ the equation of the tangent is

$$\begin{aligned} \frac{y - \left(-\frac{1}{e}\right)}{x - (-1)} &= -\frac{2}{e} \\ \therefore \frac{y + \frac{1}{e}}{x + 1} &= -\frac{2}{e} \\ \therefore e\left(y + \frac{1}{e}\right) &= -2(x + 1) \\ ey + 1 &= -2x - 2 \\ \therefore ey &= -2x - 3 \end{aligned}$$

10 a $f(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}x^2}$

$$\therefore f'(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}x^2} (-x)$$

$$= \frac{-x}{\sqrt{2\pi}} e^{-\frac{1}{2}x^2}$$

$\therefore f'(x) = 0$ when $x = 0$

$f'(x)$ has sign diagram:

Now $f(0) = \frac{1}{\sqrt{2\pi}}$

so there is a local maximum at $\left(0, \frac{1}{\sqrt{2\pi}}\right)$.

The function is increasing for $x \leq 0$ and decreasing for $x \geq 0$

b $f'(x) = \frac{-x}{\sqrt{2\pi}} e^{-\frac{1}{2}x^2} = \frac{1}{\sqrt{2\pi}} \left(-xe^{-\frac{1}{2}x^2}\right)$

REVIEW SET 19A

- 1** Consider $y = -2x^2$.

When $x = -1$, $y = -2(-1)^2 = -2$, so the point of contact is $(-1, -2)$.

$$\text{Now } \frac{dy}{dx} = -4x$$

$$\therefore \text{ the tangent has equation } \frac{y - (-2)}{x - (-1)} = 4$$

$$\therefore \text{ at } x = -1, \frac{dy}{dx} = -4(-1) = 4$$

$$\text{or } y = 4x + 2$$

2 Consider $y = \frac{1-2x}{x^2}$.

When $x = 1$, $y = \frac{1-2(1)}{1^2} = -1$, so the point of contact is $(1, -1)$.

Since $y = \frac{1}{x^2} - \frac{2}{x}$, $\frac{dy}{dx} = -2x^{-3} + 2x^{-2} = -\frac{2}{x^3} + \frac{2}{x^2}$

$\therefore$ at $x = 1$, $\frac{dy}{dx} = -2 + 2 = 0$

So, the tangent is a horizontal line, and the normal must be a vertical line of the form $x = k$.

As the normal passes through $(1, -1)$, its equation must be $x = 1$.

3 a The vertical asymptote is
 $x + 3 = 0$ or $x = -3$.

b When $y = 0$, $\frac{3x-2}{x+3} = 0$

$\therefore 3x - 2 = 0$

$\therefore x = \frac{2}{3}$

$\therefore$ the x -intercept is $\frac{2}{3}$.

When $x = 0$, $f(0) = \frac{-2}{3}$

$\therefore$ the y -intercept is $-\frac{2}{3}$.

c $f'(x) = \frac{3(x+3) - (3x-2)(1)}{(x+3)^2}$ {quotient rule}

$= \frac{3x+9-3x+2}{(x+3)^2}$

$= \frac{11}{(x+3)^2}$

$f'(x)$ has sign diagram: 

d $f'(x) \neq 0$ for any x , so $f(x)$ has no stationary points.

4 $y = e^{-x^2}$ so when $x = 1$, $y = e^{-1} = \frac{1}{e}$

$\therefore$ the point of contact is $\left(1, \frac{1}{e}\right)$

Now $\frac{dy}{dx} = -2xe^{-x^2}$

$\therefore$ when $x = 1$, $\frac{dy}{dx} = -2e^{-1}$

$\therefore$ the gradient of the tangent is $-\frac{2}{e}$

and the gradient of the normal is $\frac{e}{2}$

$\therefore$ the equation of the normal is $\frac{y - \frac{1}{e}}{x - 1} = \frac{e}{2}$

$\therefore 2\left(y - \frac{1}{e}\right) = e(x - 1)$

$\therefore 2y - \frac{2}{e} = ex - e$

$\therefore 2y = ex + \frac{2}{e} - e$

$\therefore y = \frac{e}{2}x + \frac{1}{e} - \frac{e}{2}$

5 $y = x \tan x$

$\therefore \frac{dy}{dx} = 1 \times \tan x + x \times \left(\frac{1}{\cos^2 x}\right)$

$= \tan x + \frac{x}{\cos^2 x}$

Now $\cos \frac{\pi}{4} = \frac{1}{\sqrt{2}}$ and $\tan \frac{\pi}{4} = 1$

$\therefore$ at $x = \frac{\pi}{4}$, $y = \frac{\pi}{4}$,

and $\frac{dy}{dx} = 1 + \frac{\frac{\pi}{4}}{\left(\frac{1}{\sqrt{2}}\right)^2} = 1 + \frac{\pi}{2}$

$\therefore$ the equation of the tangent is

$\frac{y - \frac{\pi}{4}}{x - \frac{\pi}{4}} = 1 + \frac{\pi}{2}$

$\therefore y - \frac{\pi}{4} = \left(1 + \frac{\pi}{2}\right)\left(x - \frac{\pi}{4}\right)$
 $= x - \frac{\pi}{4} + \frac{\pi}{2}x - \frac{\pi^2}{8}$

$\therefore y = \left(1 + \frac{\pi}{2}\right)x - \frac{\pi^2}{8}$

$\therefore 2y = (2 + \pi)x - \frac{\pi^2}{4}$

$\therefore (2 + \pi)x - 2y = \frac{\pi^2}{4}$ as required

$$\begin{aligned} 6 \quad y &= \frac{ax+b}{\sqrt{x}} = a\sqrt{x} + \frac{b}{\sqrt{x}} = ax^{\frac{1}{2}} + bx^{-\frac{1}{2}} \\ \therefore \frac{dy}{dx} &= \frac{a}{2}x^{-\frac{1}{2}} - \frac{b}{2}x^{-\frac{3}{2}} = \frac{a}{2\sqrt{x}} - \frac{b}{2x\sqrt{x}} \end{aligned}$$

The equation of the tangent at $x = 1$

$$\text{is } 2x - y = 1$$

$$\text{or } y = 2x - 1$$

so the gradient of the tangent is 2

$$\therefore \text{ at } x = 1, \quad \frac{dy}{dx} = \frac{a}{2} - \frac{b}{2} = 2$$

$$\therefore a - b = 4$$

$$\therefore a = b + 4 \quad \dots (1)$$

Also at $x = 1$, the tangent touches the curve

$$\therefore \frac{a(1)+b}{\sqrt{1}} = 2(1) - 1$$

$$\therefore a + b = 1$$

$$\therefore b + 4 + b = 1 \quad \{\text{using (1)}\}$$

$$\therefore 2b = -3$$

$$\therefore b = -\frac{3}{2} \quad \text{and} \quad a = 4 - \frac{3}{2} = \frac{5}{2}$$

$$\therefore f(x) \text{ is decreasing for } x < 1 \quad \text{and} \quad 1 < x \leq 2, \quad \text{and increasing for } x \geq 2.$$

$$f''(x) = \frac{[e^x(x-2) + e^x(1)](x-1)^2 - e^x(x-2)[2(x-1)^1(1)]}{(x-1)^4} \quad \{\text{product and quotient rules}\}$$

$$= \frac{[e^x(x-2+1)(x-1)^2] - 2e^x(x-2)(x-1)}{(x-1)^4}$$

$$= \frac{e^x(x-1)(x-1)^2 - 2e^x(x-2)(x-1)}{(x-1)^4}$$

$$= \frac{e^x(x-1)[(x-1)^2 - 2(x-2)]}{(x-1)^4}$$

$$= \frac{e^x(x-1)[x^2 - 2x + 1 - 2x + 4]}{(x-1)^4}$$

$$= \frac{e^x(x^2 - 4x + 5)}{(x-1)^3} \quad \text{where the quadratic term has } \Delta < 0$$

The sign diagram of $f''(x)$ is:

$$\therefore f''(x) > 0 \quad \text{for } x > 1$$

$$\text{and } f''(x) < 0 \quad \text{for } x < 1.$$

$$\therefore f(x) \text{ is concave down for all } x < 1$$

$$\text{and concave up for all } x > 1.$$

$$7 \quad f(x) = 4 \ln(2x), \quad P(1, 4 \ln 2)$$

$$\therefore f'(x) = 4 \times \frac{2}{2x}$$

$$= \frac{4}{x}$$

$$\therefore \text{ at } x = 1, \quad f'(1) = \frac{4}{1} = 4$$

$\therefore$ the tangent has equation

$$\frac{y - 4 \ln 2}{x - 1} = 4$$

$$\therefore y - 4 \ln 2 = 4x - 4$$

$$\therefore y = 4x + 4 \ln 2 - 4$$

e Now $f(2) = \frac{e^2}{2-1} = e^2$

Using **c**, we have a local minimum at $(2, e^2)$

$\therefore$ the tangent at $x = 2$ is horizontal
and is $y = e^2$.

9 $y = \frac{a}{(x+2)^2} = a(x+2)^{-2}$

The gradient of the line (AB) is

$$\frac{y_2 - y_1}{x_2 - x_1} = \frac{8 - 4}{0 - 2} = \frac{4}{-2} = -2$$

$\therefore$ the equation of the tangent is

$$\frac{y - 8}{x - 0} = -2 \quad \text{or} \quad y = -2x + 8$$

Now $\frac{dy}{dx} = -2a(x+2)^{-3}$, so for the given

tangent, $-2a(x+2)^{-3} = -2$

$$\therefore \frac{a}{(x+2)^3} = 1$$

$$\therefore a = (x+2)^3 \quad \dots (1)$$

The line (AB) meets the curve where

$$-2x + 8 = \frac{a}{(x+2)^2}$$

$$\therefore -2x + 8 = \frac{(x+2)^3}{(x+2)^2} \quad \{\text{using (1)}\}$$

$$\therefore -2x + 8 = x + 2$$

$$\therefore -3x = -6$$

$$\therefore x = 2$$

$$\text{and so } a = (2+2)^3 = 64$$

10 $y = \frac{5}{\sqrt{x}} = 5x^{-\frac{1}{2}}$

$$\therefore \frac{dy}{dx} = -\frac{5}{2}x^{-\frac{3}{2}}$$

$\therefore$ the gradient of the tangent at the point

$$(1, 5) \text{ is } -\frac{5}{2}(1)^{-\frac{3}{2}} = -\frac{5}{2}$$

$\therefore$ the equation of the tangent is

$$\frac{y - 5}{x - 1} = -\frac{5}{2}$$

$$\therefore y - 5 = -\frac{5}{2}x + \frac{5}{2}$$

$$\therefore y = -\frac{5}{2}x + \frac{15}{2}$$

Now, P and Q are the y - and x -intercepts, so:

$$\begin{aligned} \text{P: } y &= -\frac{5}{2}(0) + \frac{15}{2} \\ &= \frac{15}{2} \end{aligned}$$

$$\text{Q: } 0 = -\frac{5}{2}x + \frac{15}{2}$$

$$\therefore \frac{5}{2}x = \frac{15}{2}$$

$$\therefore x = 3$$

So P is $(0, 7.5)$ and Q is $(3, 0)$.

11 At $x = A$, $f'(x) = 0$ and $f''(x) = 0$

$\therefore f(x)$ has a stationary inflection point at $x = A$.

At $x = B$, $f''(x) = 0$ but $f'(x) \neq 0$

$\therefore f(x)$ has a non-stationary inflection point at $x = B$.

$f'(x)$ is above the x -axis for $x \leq C$, and below the x -axis for $x \geq C$

$\therefore f(x)$ is increasing for $x \leq C$ and decreasing for $x \geq C$, so $f(x)$ has a local maximum at $x = C$.

12 $y = \ln(x^2 + 3) \quad \therefore \frac{dy}{dx} = \frac{2x}{x^2 + 3}$

When $x = 0$, $\frac{dy}{dx} = 0$ so the gradient of the tangent at this point is 0.

But when $x = 0$, $y = \ln(0 + 3) = \ln 3$

$\therefore$ the tangent is $y = \ln 3$ which does not cut the x -axis.

13 a $y = \sec x = \frac{1}{\cos x}$

When $x = \frac{\pi}{3}$, then $y = \frac{1}{\cos \frac{\pi}{3}} = \frac{1}{\frac{1}{2}} = 2$

$$\frac{dy}{dx} = \sec x \tan x = \frac{1}{\cos x} \frac{\sin x}{\cos x}$$

When $x = \frac{\pi}{3}$, then $\frac{dy}{dx} = \frac{\sin \frac{\pi}{3}}{(\cos \frac{\pi}{3})^2}$

$$= \frac{\frac{\sqrt{3}}{2}}{(\frac{1}{2})^2}$$

$$= \frac{\sqrt{3}}{2} \times \frac{4}{1}$$

$$= 2\sqrt{3}$$

$\therefore$ the equation of the tangent at $(\frac{\pi}{3}, 2)$ is:

$$\frac{y-2}{x-\frac{\pi}{3}} = 2\sqrt{3}$$

$$\therefore y-2 = 2\sqrt{3}x - \frac{2\sqrt{3}\pi}{3}$$

$$\therefore 2\sqrt{3}x - y = \frac{2\sqrt{3}\pi}{3} - 2$$

b $y = \arctan x$

When $x = \sqrt{3}$, then $y = \arctan \sqrt{3} = \frac{\pi}{3}$

$$\frac{dy}{dx} = \frac{1}{1+x^2}, \quad x \in \mathbb{R}$$

When $x = \sqrt{3}$, then $\frac{dy}{dx} = \frac{1}{1+\sqrt{3}^2}$

$$= \frac{1}{1+3}$$

$$= \frac{1}{4}$$

$\therefore$ the gradient of the normal is -4

$\therefore$ the equation of the normal at $(\sqrt{3}, \frac{\pi}{3})$ is:

$$\frac{y-\frac{\pi}{3}}{x-\sqrt{3}} = -4$$

$$\therefore y - \frac{\pi}{3} = -4x + 4\sqrt{3}$$

$$\therefore 4x + y = 4\sqrt{3} + \frac{\pi}{3}$$

14 $x^2 + y^2 = 1$

$$\therefore y^2 = 1 - x^2$$

$$\therefore y = (1 - x^2)^{\frac{1}{2}} = \pm \sqrt{1 - x^2}, \quad x \in [-1, 1]$$

For any point on the circle let $x = a$, then $y = \pm \sqrt{1 - a^2}$, $a \in [-1, 1]$

If $y > 0$, $\frac{dy}{dx} = \frac{1}{2}(1 - x^2)^{-\frac{1}{2}}(-2x) = \frac{-x}{\sqrt{1 - x^2}}, \quad x \in [-1, 1]$

$\therefore$ the gradient of the normal would be $\frac{\sqrt{1 - x^2}}{x}$

$\therefore$ for the points $(a, \sqrt{1 - a^2})$ the gradient is $\frac{\sqrt{1 - a^2}}{a}$

$\therefore$ the equation of the normal at $(a, \sqrt{1 - a^2})$ is:

$$\frac{y - \sqrt{1 - a^2}}{x - a} = \frac{\sqrt{1 - a^2}}{a}$$

$$\therefore ay - a\sqrt{1 - a^2} = x\sqrt{1 - a^2} - a\sqrt{1 - a^2}$$

$$\therefore y = \frac{\sqrt{1 - a^2}}{a}x$$

which for any $a \in [-1, 1]$ will pass through the origin.

If $y < 0$, $\frac{dy}{dx} = \frac{x}{\sqrt{1 - x^2}}, \quad x \in [-1, 1]$

$\therefore$ the gradient of the normal is $-\frac{\sqrt{1 - x^2}}{x}$

$\therefore$ for the points $(a, -\sqrt{1 - a^2})$ the gradient is $-\frac{\sqrt{1 - a^2}}{a}$

$\therefore$ the equation of the normal at $(a, -\sqrt{1 - a^2})$ is:

$$\frac{y + \sqrt{1 - a^2}}{x - a} = -\frac{\sqrt{1 - a^2}}{a}$$

$$\therefore y = -\frac{\sqrt{1 - a^2}}{a}x \quad \text{which will pass through the origin for any } a \in [-1, 1].$$

$$4 \quad f(x) = e^{4x} + px + q$$

$$\therefore f'(x) = 4e^{4x} + p$$

At the point where $x = 0$, the tangent to $f(x)$ has equation $y = 5x - 7$, so $f'(0) = 5$
 $\therefore 4e^0 + p = 5$
 $\therefore p = 1$

The tangent meets $f(x)$ when $x = 0$ and $y = 5(0) - 7 = -7$, so $(0, -7)$ must lie on $f(x)$ too.

$$\therefore e^{4(0)} + p(0) + q = -7$$

$$\therefore 1 + q = -7$$

$$\therefore q = -8$$

5 Consider the tangent to $y = 2x^3 + 4x - 1$ at $(1, 5)$.

$$\frac{dy}{dx} = 6x^2 + 4 \quad \therefore \text{ at } x = 1, \quad \frac{dy}{dx} = 6(1)^2 + 4 = 10$$

$$\therefore \text{ the tangent has equation } \frac{y - 5}{x - 1} = 10 \quad \text{or} \quad y = 10x - 5$$

Now the tangent meets the curve again where $10x - 5 = 2x^3 + 4x - 1$

$$\therefore 2x^3 - 6x + 4 = 0$$

$$\therefore x^3 - 3x + 2 = 0$$

We know that $(x - 1)^2$ is a factor since the line is tangent to the curve at $x = 1$.

Consequently, $x^3 - 3x + 2 = (x - 1)^2(x + 2) = 0$ {since the constant term is 2}

Thus $x = -2$ is the other solution and when $x = -2$, $y = 2(-2)^3 + 4(-2) - 1 = -25$

$\therefore$ the tangent meets the curve again at $(-2, -25)$.

6 Consider $y = 4(ax + 1)^{-2}$.

When $x = 0$, $y = 4(0 + 1)^{-2} = 4$, so the point of contact is $(0, 4)$.

$$\text{Now } \frac{dy}{dx} = -8(ax + 1)^{-3}(a) = \frac{-8a}{(ax + 1)^3} \quad \therefore \text{ at } x = 0, \quad \frac{dy}{dx} = -8a$$

$$\therefore \text{ the tangent has equation } \frac{y - 4}{x - 0} = -8a \quad \text{or} \quad y - 4 = -8ax$$

This tangent passes through $(1, 0)$, so $0 - 4 = -8a(1) \quad \therefore a = \frac{1}{2}$

7 $f(x) = e^x - x$

a $f'(x) = e^x - 1$

so $f'(x) = 0$ when $e^x = 1$

$$\therefore x = 0$$

b As $x \rightarrow \infty$, $e^x \rightarrow \infty$ faster than x

$$\therefore f(x) \rightarrow \infty$$

Sign diagram of $f'(x)$ is:

$$\text{Now } f(0) = e^0 - 0 = 1$$

$\therefore$ there is a local minimum at $(0, 1)$.

c $f''(x) = e^x$

$$\therefore f''(x) > 0 \quad \text{for all } x$$

$$\longleftarrow \xrightarrow{+} x$$

$\therefore f(x)$ is concave up for all x

e Since a local minimum exists at $(0, 1)$,

$$f(x) \geq 1 \quad \text{for all } x$$

$$\therefore e^x - x \geq 1$$

$$\therefore e^x \geq x + 1 \quad \text{for all } x$$

8 Consider $y = \frac{x+1}{x^2-2}$.

When $x = 1$, $y = \frac{1+1}{1^2-2} = -2$

$\therefore$ the point of contact is $(1, -2)$.

$y = \frac{x+1}{x^2-2}$ is a quotient with $u = x+1$ and $v = x^2-2$
 $\therefore u' = 1$ and $v' = 2x$

$\frac{dy}{dx} = \frac{1(x^2-2) - (x+1)(2x)}{(x^2-2)^2}$ {quotient rule}

$\therefore$ at $x = 1$, $\frac{dy}{dx} = \frac{(1-2) - 2(1+1)}{(1-2)^2}$
 $= \frac{-1-4}{1} = -5$

$\therefore$ the normal at $(1, -2)$ has gradient $\frac{1}{5}$.

So the normal has equation $\frac{y - (-2)}{x - 1} = \frac{1}{5}$

$\therefore 5y + 10 = x - 1$

$\therefore y = \frac{1}{5}x - \frac{11}{5}$ (or $x - 5y = 11$)

9 $y = 2 - \frac{7}{1+2x} = 2 - 7(1+2x)^{-1}$

$\therefore \frac{dy}{dx} = 7(1+2x)^{-2} \times 2$ {chain rule}
 $= \frac{14}{(1+2x)^2}$

The tangent is horizontal when the gradient $\frac{dy}{dx} = 0$.

But $\frac{14}{(1+2x)^2}$ is never 0, so

$y = 2 - \frac{7}{1+2x}$ has no horizontal tangents.

10 Let $g(x) = ax^2 + bx + c$.

$g(x)$ has y -intercept $(0, 3)$, so $g(0) = a(0)^2 + b(0) + c = 3$
 $\therefore c = 3$

$\therefore g(x) = ax^2 + bx + 3$

The point $(2, 7)$ lies on $g(x)$, so $g(2) = a(2)^2 + b(2) + 3 = 7$
 $\therefore 4a + 2b = 4$ (1)

Also, $g'(x) = 2ax + b$

$\therefore g'(2) = 2a(2) + b = 4a + b$

$\therefore$ the gradient of the tangent to $g(x)$ at $(2, 7)$ is $4a + b$.

But, the tangent at $(2, 7)$ passes through $(0, 11)$, so the gradient $= \frac{7-11}{2-0} = -2$

$\therefore 4a + b = -2$ (2)

Solving (1) and (2) simultaneously, $4a + 2b = 4$
 $4a + b = -2$
 subtracting: $b = 6$

Using (2), $4a + 6 = -2$, so $a = -2$

So, $g(x) = -2x^2 + 6x + 3$

 $f(x)$ is decreasing for $x \leq 0$,
 except at the asymptote,

 As $x \rightarrow \pm\infty$, $f(x)$ becomes

1 Consider the normal to the curve $y = \frac{1}{\sqrt{x}}$ at $x = 4$.

When $x = 4$, $y = \frac{1}{\sqrt{4}} = \frac{1}{2}$, so the point of contact is $(4, \frac{1}{2})$.

Now $\frac{dy}{dx} = -\frac{1}{2}x^{-\frac{3}{2}}$ $\therefore$ at $x = 4$, $\frac{dy}{dx} = -\frac{1}{2}\left(4^{-\frac{3}{2}}\right) = -\frac{1}{2}\left(\frac{1}{8}\right) = -\frac{1}{16}$

$\therefore$ the normal at $(4, \frac{1}{2})$ has gradient 16.

So the equation is $\frac{y - \frac{1}{2}}{x - 4} = 16$

$$\therefore y - \frac{1}{2} = 16x - 64$$

$$\therefore y = 16x - \frac{127}{2}$$

Also, since the tangent passes through (0, 5),

it has equation $\frac{y-5}{x-0} = -1$

$$\begin{aligned} \text{As the point } (-2, 14) \text{ lies on the curve, } 14 &= 3(-2)^3 + 9(-2)^2 + b \\ \therefore b &= 14 + 24 - 36 \\ \therefore b &= 2 \end{aligned}$$

$$\therefore f'(x) = 9x^2 + 18x$$

$$\therefore f''(x) = 18x + 18 \text{ and so } f''(-2) = -36 + 18 = -18$$

$$\mathbf{11} \quad \text{The curves } y = \sqrt{3x+1} \text{ and } y = \sqrt{5x-x^2} \text{ meet when } \sqrt{3x+1} = \sqrt{5x-x^2}$$

$$\text{Squaring both sides, } 3x+1 = 5x-x^2$$

$$\therefore x^2 - 2x + 1 = 0$$

$$\therefore (x-1)^2 = 0$$

$$\therefore x = 1$$

$$\text{When } x = 1, \quad y = \sqrt{3+1} = 2, \text{ so the curves meet at } (1, 2).$$

Now for

$$y = \sqrt{3x + 1} = (3x + 1)^{\frac{1}{2}}$$

$$\frac{dy}{dx} = \frac{1}{2}(3x + 1)^{-\frac{1}{2}}(3)$$

$\therefore$ at $(1, 2)$, $\frac{dy}{dx} = \frac{3}{2(3 + 1)^{\frac{1}{2}}} = \frac{3}{4}$

Check:

$$y = \sqrt{5x - x^2} = (5x - x^2)^{\frac{1}{2}}$$

$$\frac{dy}{dx} = \frac{1}{2}(5x - x^2)^{-\frac{1}{2}}(5 - 2x) = \frac{5 - 2x}{2\sqrt{5x - x^2}}$$

$\therefore$ at $(1, 2)$, $\frac{dy}{dx} = \frac{5 - 2}{2\sqrt{5 - 1}} = \frac{3}{4} \quad \checkmark$

$\therefore$ the curves have a common tangent at their point of intersection.

The equation of the common tangent at $(1, 2)$ is

$$\frac{y - 2}{x - 1} = \frac{3}{4}$$

$\therefore 4(y - 2) = 3(x - 1)$

$\therefore 4y = 3x + 5$

12 a $f(x) = x + \ln x$ is defined when $x > 0$

b $f'(x) = 1 + \frac{1}{x} = \frac{x + 1}{x}$ which has sign diagram:

$+$

x

$\therefore f(x)$ is increasing for all $x > 0$.

$f''(x) = -\frac{1}{x^2}$ which has sign diagram:

$-$

x

$\therefore f(x)$ is concave down for all $x > 0$.

d $f(1) = 1 + \ln(1) = 1$

$\therefore (1, 1)$ is the point of contact.

$f'(1) = \frac{1 + 1}{1} = 2$

$\therefore$ the tangent at $x = 1$ has gradient 2,
so the normal has gradient $-\frac{1}{2}$

$\therefore$ the normal has equation $\frac{y - 1}{x - 1} = -\frac{1}{2}$

$\therefore 2y - 2 = -x + 1$

$\therefore x + 2y = 3$

13 At $x = B$, $f''(x) = 0$ but $f'(x) \neq 0$

$\therefore f(x)$ has a non-stationary inflection point at $x = B$.

$f'(x)$ is above the x -axis for $x \leq A$ and $x \geq C$, and below the x -axis for $A \leq x \leq C$

$\therefore f(x)$ is increasing for $x \leq A$, decreasing for $A \leq x \leq C$, then increasing for $x \geq C$

$\therefore f(x)$ has a local maximum at $x = A$ and a local minimum at $x = C$.

14 $f(x) = \arcsin x + \arccos x$

$$f'(x) = \frac{1}{\sqrt{1-x^2}} + \left(\frac{-1}{\sqrt{1-x^2}} \right), \quad x \in]-1, 1[$$

$$= 0$$

$\therefore$ the gradient of the function is zero.

$$f(0) = \arcsin(0) + \arccos(0)$$

$$= 0 + \frac{\pi}{2}$$

$\therefore f(x) = \frac{\pi}{2}$, a constant.

15 a $x^2 + y^2 = 4$

$$\therefore y = \pm\sqrt{4-x^2} = \pm(4-x^2)^{\frac{1}{2}}$$

$$\therefore \frac{dy}{dx} = \pm\frac{1}{2}(4-x^2)^{-\frac{1}{2}}(-2x)$$

$$= \frac{\mp x}{\sqrt{4-x^2}}$$

$$\therefore \text{ when } y = (4-x^2)^{\frac{1}{2}}, \quad \frac{dy}{dx} = \frac{-x}{\sqrt{4-x^2}}$$

$$\text{and when } y = -(4-x^2)^{\frac{1}{2}}, \quad \frac{dy}{dx} = \frac{x}{\sqrt{4-x^2}}$$

When $y = 1$, then $x^2 + 1^2 = 4$

$$\therefore x^2 = 3$$

$$\therefore x = \pm\sqrt{3}$$

At the point $(\sqrt{3}, 1)$, $\frac{dy}{dx} = \frac{-\sqrt{3}}{\sqrt{4-\sqrt{3}^2}} = \frac{-\sqrt{3}}{1} = -\sqrt{3}$

At the point $(-\sqrt{3}, 1)$, $\frac{dy}{dx} = \frac{-(-\sqrt{3})}{\sqrt{4-(-\sqrt{3})^2}} = \frac{\sqrt{3}}{1} = \sqrt{3}$

$\therefore$ the equation of the tangent at $(\sqrt{3}, 1)$, is:

$$\frac{y-1}{x-\sqrt{3}} = -\sqrt{3}$$

$$\therefore y-1 = -\sqrt{3}x+3$$

$$\therefore \sqrt{3}x+y=4$$

$\therefore$ the equation of the tangent at $(-\sqrt{3}, 1)$ is:

$$\frac{y-1}{x-(-\sqrt{3})} = \sqrt{3}$$

$$\therefore y-1 = \sqrt{3}(x+\sqrt{3})$$

$$\therefore y-1 = \sqrt{3}x+3$$

$$\therefore \sqrt{3}x-y=-4$$

b The tangents intersect when $\sqrt{3}x = 4-y$, $\sqrt{3}x = -4+y$

$$\therefore 4-y = -4+y$$

$$\therefore 8 = 2y$$

$$\therefore y = 4$$

When $y = 4$, then $\sqrt{3}x = 4-4$

$$\therefore \sqrt{3}x = 0$$

$$\therefore x = 0$$

$\therefore$ the tangents intersect at $(0, 4)$.

This is the instantaneous acceleration at t seconds.

4 a This is the instantaneous velocity at $t = 4$ seconds.

b This is the instantaneous acceleration at $t = 4$ seconds.

EXERCISE 20A.2

1 a $s(t) = t^2 - 4t + 3 \text{ cm}, t \geq 0 \quad \therefore v(t) = 2t - 4 \text{ cm s}^{-1} \text{ and } a(t) = 2 \text{ cm s}^{-2}.$

b When $t = 0$, $s(0) = 3 \text{ cm}$
 $v(0) = -4 \text{ cm s}^{-1}$
 $a(0) = 2 \text{ cm s}^{-2}$

$\therefore$ the object is 3 cm right of O and is moving to the left with a velocity of 4 cm s^{-1} and slowing down, its acceleration being 2 cm s^{-2} to the right.

c When $t = 2$, $s(2) = -1 \text{ cm}$
 $v(2) = 0 \text{ cm s}^{-1}$
 $a(2) = 2 \text{ cm s}^{-2}$

$\therefore$ the object is 1 cm left of O, instantaneously stationary and accelerating to the right at 2 cm s^{-2} .

d The object reverses direction when $v(t) = 0$, which occurs at $t = 2$ seconds.
 At $t = 2$, the particle is 1 cm left of O.

e

f Speed decreases when $v(t)$ and $a(t)$ have opposite signs, which is when $0 \leq t \leq 2$.

2 $s(t) = 98t - 4.9t^2$ m, $t \geq 0$

a $v(t) = 98 - 9.8t$ m s⁻¹
 $a(t) = -9.8$ m s⁻²

b When $t = 0$, $s(0) = 0$ m, $v(0) = 98$ m s⁻¹ skyward

c When $t = 5$, $s(5) = 367.5$ m The stone is 367.5 m above the ground and moving
 $v(5) = 49$ m s⁻¹ skyward at 49 m s⁻¹. Its speed is decreasing.
 $a(5) = -9.8$ m s⁻²

When $t = 12$, $s(12) = 470.4$ m The stone is 470.4 m above the ground and moving
 $v(12) = -19.6$ m s⁻¹ groundward at 19.6 m s⁻¹. Its speed is increasing.
 $a(12) = -9.8$ m s⁻²

d The maximum height is reached when $v(t) = 0$ m s⁻¹ $\therefore$ the maximum height is
 $\therefore 98 - 9.8t = 0$ $s(10) = 98(10) - 4.9(100)$
 $\therefore 9.8t = 98$ $= 980 - 490$
 $\therefore t = 10$ seconds $= 490$ m

e The stone is at ground level when $s(t) = 0$ which is when $98t - 4.9t^2 = 0$
 $\therefore 4.9t(20 - t) = 0$
 $\therefore t = 0$ or 20 seconds
 $\therefore$ it hits the ground after 20 seconds.

3 $s(t) = 1.2 + 28.1t - 4.9t^2$ metres

a When released, $t = 0$ and $s(0) = 1.2$ m $\therefore$ it is released 1.2 m above the ground.

b $s'(t) = 28.1 - 9.8t$ m s⁻¹ is the instantaneous velocity of the ball at the time t seconds after release.

c When $s'(t) = 0$, $28.1 - 9.8t = 0$ $\therefore t = \frac{28.1}{9.8} \approx 2.87$ seconds

So, after 2.87 seconds the ball has reached its maximum height, and is instantaneously at rest.

d $s(2.867) = 1.2 + 28.1 \times 2.867 - 4.9 \times 2.867^2 \approx 41.5$ m

So, the maximum height reached is about 41.5 m.

e i $s'(0) = 28.1$ m s⁻¹ ii $s'(2) = 28.1 - 19.6$ iii $s'(5) = 28.1 - 49$
 $= 8.5$ m s⁻¹ $= -20.9$ m s⁻¹
 $\therefore$ speed = 20.9 m s⁻¹

If $s'(t) \geq 0$, the ball is travelling upwards. If $s'(t) \leq 0$, the ball is travelling downwards.

f $s(t) = 0$ when $1.2 + 28.1t - 4.9t^2 = 0$
 $\therefore 4.9t^2 - 28.1t - 1.2 = 0$
 $\therefore t = \frac{28.1 \pm \sqrt{28.1^2 - 4(4.9)(-1.2)}}{9.8} \approx -0.0424$ or 5.777

But $t > 0$, so the ball hits the ground after 5.78 seconds.

g $s''(t) = -9.8$ m s⁻² and is the rate of change in $s'(t)$
 $\therefore$ the instantaneous acceleration is constant at -9.8 m s⁻² for the entire motion.

4 a $s(t) = bt - 4.9t^2$
 $s'(t) = b - 9.8t$
 $\therefore s'(0) = b$
 $\therefore$ the initial velocity is b m s⁻¹ upwards.

b Since $s(14.2) = 0$,
 $b(14.2) - 4.9(14.2)^2 = 0$
 $\therefore 14.2[b - 4.9 \times 14.2] = 0$
 $\therefore b = 4.9 \times 14.2$
 $\therefore b = 69.58$
 $\therefore$ the initial velocity is 69.6 m s⁻¹.

- 5 a $s(t) = 12t - 2t^3 - 1$ cm, $t \geq 0$
 $\therefore v(t) = 12 - 6t^2$ cm s⁻¹
 and $a(t) = -12t$ cm s⁻²

- b When $t = 0$, $s(0) = -1$ cm The particle was 1 cm left of O and was moving right at a constant speed of 12 cm s⁻¹.
 $v(0) = 12$ cm s⁻¹
 $a(0) = 0$ cm s⁻²

- c The particle reverses direction when $v(t) = 0$ which is when $12 - 6t^2 = 0$
 $\therefore t^2 = 2$
 $\therefore t = \sqrt{2}$ $\{t > 0\}$

When $t = \sqrt{2}$, $s(\sqrt{2}) = 12\sqrt{2} - 2(2\sqrt{2}) - 1$
 $= 8\sqrt{2} - 1$

$\therefore$ the particle is $(8\sqrt{2} - 1)$ cm to the right of O.

- d i From the sign diagrams in a, the speed increases for $t \geq \sqrt{2}$ seconds.
 ii The velocity of the particle never increases $\{a(t) \leq 0\}$.

- 6 a $x(t) = t^3 - 9t^2 + 24t$ m, $t \geq 0$
 $v(t) = 3t^2 - 18t + 24$ and $a(t) = 6t - 18$
 $= 3(t^2 - 6t + 8)$ $= 6(t - 3)$ m s⁻²
 $= 3(t - 4)(t - 2)$ m s⁻¹

- b The particle reverses direction when $v(t) = 0$, which occurs at $t = 2$ and $t = 4$ seconds.
 $x(2) = 8 - 36 + 48$ m and $x(4) = 64 - 144 + 96$
 $= 20$ m $= 16$ m

- c i The speed decreases when $v(t)$ and $a(t)$ have the opposite sign, which is when $0 \leq t \leq 2$ and $3 \leq t \leq 4$.
 ii The velocity decreases when $a(t) \leq 0$, which is when $0 \leq t \leq 3$.
 d When $t = 5$, $x(5) = 5^3 - 9(5)^2 + 24(5)$ $\therefore$ distance travelled $= 20 + 4 + 4$ m
 $= 125 - 225 + 120$ $= 28$ m
 $= 20$ m

- 7 a $s(t) = 100t + 200e^{-\frac{t}{5}}$ cm, $t \geq 0$ b When $t = 0$, $s(0) = 200$ cm (right of the origin)
 $v(t) = 100 - 40e^{-\frac{t}{5}}$ cm s⁻¹ $v(0) = 60$ cm s⁻¹
 $a(t) = 8e^{-\frac{t}{5}}$ cm s⁻² $a(0) = 8$ cm s⁻²

- c As $t \rightarrow \infty$, $e^{-\frac{t}{5}} \rightarrow 0$,
 $\therefore v(t) \rightarrow 100$ cm s⁻¹ (below)

- e When $v(t) = 80$ cm s⁻¹,
 $100 - 40e^{-\frac{t}{5}} = 80$
 $\therefore -40e^{-\frac{t}{5}} = -20$
 $\therefore e^{-\frac{t}{5}} = 0.5$
 $\therefore -\frac{t}{5} = \ln 0.5$
 $\therefore t = -5 \ln 0.5 \approx 3.47$ s

8 $x(t) = 1 - 2 \cos t$ cm
 $\therefore v(t) = x'(t) = 2 \sin t$
 $\therefore a(t) = v'(t) = 2 \cos t$

a When $t = 0$,
 $x(0) = 1 - 2 \cos 0$
 $= -1$ cm
 $v(0) = 2 \sin 0$
 $= 0$ cm s⁻¹
 $a(0) = 2 \cos 0$
 $= 2$ cm s⁻²

b When $t = \frac{\pi}{4}$,
 $x(\frac{\pi}{4}) = 1 - \frac{2}{\sqrt{2}}$
 $= 1 - \sqrt{2}$ cm
 $v(\frac{\pi}{4}) = \frac{2}{\sqrt{2}} = \sqrt{2}$ cm s⁻¹
 $a(\frac{\pi}{4}) = \frac{2}{\sqrt{2}} = \sqrt{2}$ cm s⁻²

The particle is $(\sqrt{2} - 1)$ cm left of the origin, moving right at $\sqrt{2}$ cm s⁻¹ with increasing speed.

c We need to look for the points where the velocity equals zero.

If $v(t) = 2 \sin t = 0$
then $\sin t = 0$
 $\therefore t = \pi$ ($0 < t < 2\pi$)

The particle reverses direction when $t = \pi$.
At $t = \pi$, $x(\pi) = 3$ cm.

d The particle's speed is increasing when $v(t) = 2 \sin t$ and $a(t) = 2 \cos t$ have the same sign.

If $a(t) = 2 \cos t = 0$
then $\cos t = 0$
 $t = \frac{\pi}{2}, \frac{3\pi}{2}$ ($0 \leq t \leq 2\pi$)

$\therefore$ the particle's speed is increasing when $0 \leq t \leq \frac{\pi}{2}$ and $\pi \leq t \leq \frac{3\pi}{2}$.

9 a Let the equation be $s(t) = at^2 + bt + c$
 $\therefore v(t) = 2at + b$
and $a(t) = 2a = g$ {gravitational acceleration}
 $\therefore a = \frac{1}{2}g$ and $v(t) = gt + b$

But when $t = 0$, $v(0) = g \times 0 + b = b$
 $\therefore$ the initial velocity is b
 $\therefore v(t) = v(0) + gt$ as required

b Now when $t = 0$, $s(0) = 0$
 $\therefore a \times 0^2 + b \times 0 + c = 0$
 $\therefore c = 0$
and so $s(t) = (\frac{1}{2}g)t^2 + v(0)t$
 $\therefore s(t) = v(0) \times t + \frac{1}{2}gt^2$ as required

b $a(t) = v'(t)$
 $= 25 \times e^{-2t} + 25t(-2)e^{-2t}$
 $= 25(1 - 2t)e^{-2t}$ cm s⁻²

c $v'(t) = 0$ when $1 - 2t = 0$
 $\therefore t = \frac{1}{2}$

$\therefore$ the velocity is increasing for $0 \leq t \leq \frac{1}{2}$

EXERCISE 20B

1 $P(t) = 2t^2 - 12t + 118$ thousand dollars, $t \geq 0$
a $P(0) = \$118\,000$ is the current annual profit

b $\frac{dP}{dt} = 4t - 12$ thousand dollars per year

c $\frac{dP}{dt}$ is the rate of change in profit with time.

d **i** The profit decreases when $\frac{dP}{dt} \leq 0$, which occurs when $4t - 12 \leq 0$
 $\therefore 4t \leq 12$
 $\therefore t \leq 3$

But $t \geq 0$, so $0 \leq t \leq 3$ years.

ii The profit increases on the previous year when $\frac{dP}{dt} \geq 0$, which is for $t > 3$ years.

e The profit function is a quadratic with $a > 0$ $\therefore$ the shape is 

So, a minimum profit occurs when $\frac{dP}{dt} = 0$, which is when $t = 3$ years

and $P(3) = 18 - 36 + 118 = 100$ thousand dollars or \$100 000.

f When $t = 4$, $\frac{dP}{dt} = 4$ thousand dollars per year.

So, the profit is increasing at \$4000 per year after 4 years.

When $t = 10$, $\frac{dP}{dt} = 28$ thousand dollars per year.

So, the profit is increasing at \$28 000 per year after 10 years.

When $t = 25$, $\frac{dP}{dt} = 88$ thousand dollars per year.

So, the profit is increasing at \$88 000 per year after 25 years.

2 $V = 200(50 - t)^2 \text{ m}^3$

a average rate on $0 \leq t \leq 5$

$$\begin{aligned} &= \frac{V(5) - V(0)}{5 - 0} \\ &= \frac{200(45)^2 - 200(50)^2}{5} \\ &= -19\,000 \text{ m}^3 \text{ per minute} \\ &\therefore \text{leaving at } 19\,000 \text{ m}^3 \text{ per minute} \end{aligned}$$

b $V'(t) = 400(50 - t)^1 \times (-1)$
 $\therefore V'(5) = 400 \times 45 \times -1$
 $= -18\,000 \text{ m}^3 \text{ per minute}$
 $\therefore \text{leaving at } 18\,000 \text{ m}^3 \text{ per minute}$

3 $Q = 100 - 10\sqrt{t}$, $t \geq 0$

a **i** At $t = 0$, $Q = 100$ units

ii At $t = 25$, $Q = 50$ units

iii At $t = 100$, $Q = 0$ units

b $\frac{dQ}{dt} = -5t^{-\frac{1}{2}} = -\frac{5}{\sqrt{t}}$

i At $t = 25$, $\frac{dQ}{dt} = -1$ unit per year
 $\therefore$ decreasing at 1 unit per year

ii At $t = 50$, $\frac{dQ}{dt} = -\frac{5}{\sqrt{50}}$
 $= -\frac{1}{\sqrt{2}}$ units per year
 $\therefore$ decreasing at $\frac{1}{\sqrt{2}}$ units per year

c $\frac{dQ}{dt} = -\frac{5}{\sqrt{t}}$ $\therefore$ the skin *loses* the chemical at the rate $R = \frac{5}{\sqrt{t}} = 5t^{-\frac{1}{2}}$ units per year.

Now $\frac{dR}{dt} = -\frac{5}{2}t^{-\frac{3}{2}} = -\frac{5}{2t\sqrt{t}}$

Since $2t\sqrt{t} > 0$ for all $t > 0$, $\frac{dR}{dt} < 0$ for all $t > 0$.

$\therefore$ the rate at which the skin loses the chemical is decreasing for all $t > 0$.

4 $H = 20 - \frac{97.5}{t+5}$ m, $t \geq 0$

a At planting, $t = 0 \quad \therefore H(0) = 20 - \frac{97.5}{0+5} = 0.5$ m

b $H(4) = 20 - \frac{97.5}{4+5} \approx 9.17$ m

$H(8) = 20 - \frac{97.5}{8+5} = 12.5$ m

$H(12) = 20 - \frac{97.5}{12+5} \approx 14.3$ m

c Now $\frac{dH}{dt} = 97.5(t+5)^{-2} = \frac{97.5}{(t+5)^2}$

When $t = 0$, $\frac{dH}{dt} = \frac{97.5}{25} = 3.9$ m year⁻¹

When $t = 5$, $\frac{dH}{dt} = \frac{97.5}{100} = 0.975$ m year⁻¹

When $t = 10$, $\frac{dH}{dt} = \frac{97.5}{225} \approx 0.433$ m year⁻¹

d Now $\frac{dH}{dt} = \frac{97.5}{(t+5)^2}$

Since $(t+5)^2 > 0$ for all $t \geq 0$, $\frac{dH}{dt} > 0$ for all $t \geq 0$

$\therefore$ the height of the tree is always increasing, which means that the tree is always growing.

5 a $C(x) = 0.0003x^3 + 0.02x^2 + 4x + 2250$

$\therefore C'(x) = 0.0009x^2 + 0.04x + 4$ dollars per pair

b $C'(220) = 0.0009(220)^2 + 0.04(220) + 4 = \56.36 per pair

This estimates the cost of making the 221st pair of jeans if 220 pairs are currently being made.

c $C(221) - C(220) \approx \$7348.98 - \$7292.40 \approx \56.58

This is the actual cost to make the extra pair of jeans (221 instead of 220).

d $C''(x) = 0.0018x + 0.04$

$C''(x) = 0$ when $0.0018x + 0.04 = 0$

$\therefore x = -\frac{0.04}{0.0018} \approx -22.2$

This is the point when the rate of change is a minimum. However, it is out of the bounds of our model, as we cannot make a negative quantity of jeans.

6 a $C(v) = \frac{1}{5}v^2 + 200\,000v^{-1}$ euros

i At $v = 50$ km h⁻¹, $C = \frac{1}{5}(50)^2 + \frac{200\,000}{50} = \text{€}4500$

ii At $v = 100$ km h⁻¹, $C = \frac{1}{5}(100)^2 + \frac{200\,000}{100} = \text{€}4000$

b $\frac{dC}{dv} = \frac{2}{5}v - 200\,000v^{-2} = \frac{2}{5}v - \frac{200\,000}{v^2}$

i At $v = 30$ km h⁻¹,

$\frac{dC}{dv} = \frac{2}{5}(30) - \frac{200\,000}{30^2}$
 $\approx -\text{€}210.22$ per km h⁻¹

So, a decrease of €210.22 per km h⁻¹.

ii At $v = 90$ km h⁻¹,

$\frac{dC}{dv} = \frac{2}{5}(90) - \frac{200\,000}{90^2}$
 $\approx \text{€}11.31$ per km h⁻¹

So, an increase of €11.31 per km h⁻¹.

c The cost is a minimum when $\frac{dC}{dv} = 0$, which occurs when $\frac{2}{5}v - \frac{200\,000}{v^2} = 0$

$\therefore \frac{2}{5}v = \frac{200\,000}{v^2}$

$\therefore v^3 = 500\,000$

$\therefore v \approx 79.4$ km h⁻¹

7 a $V = 50\,000 \left(1 - \frac{t}{80}\right)^2, \quad 0 \leq t \leq 80$

$\therefore \frac{dV}{dt} = 2 \times 50\,000 \left(1 - \frac{t}{80}\right)^1 \times \left(-\frac{1}{80}\right) = -1250 \left(1 - \frac{t}{80}\right) \text{ L min}^{-1}$

b The outflow was fastest when $t = 0$, when the tap was first opened.

c $\frac{dV}{dt} = -1250 + \frac{1250}{80}t \quad \therefore \frac{d^2V}{dt^2} = \frac{1250}{80} = \frac{125}{8} \text{ L min}^{-2}$

Since $\frac{d^2V}{dt^2}$ is constant and positive, $\frac{dV}{dt}$ is constantly increasing

$\therefore$ the outflow is decreasing at a constant rate.

8 $y = \frac{1}{10}x(x-2)(x-3) = \frac{1}{10}(x^3 - 5x^2 + 6x)$

a When $y = 0$, $x = 0, 2$, or 3

$\therefore$ the lake is between 2 and 3 km from the shoreline.

b $\frac{dy}{dx} = \frac{1}{10}(3x^2 - 10x + 6)$
 $= \frac{3}{10}x^2 - x + \frac{3}{5}$

When $x = \frac{1}{2}$, $\frac{dy}{dx} = \frac{7}{40} = 0.175 \quad \therefore$ land is sloping upwards.

When $x = 1\frac{1}{2}$, $\frac{dy}{dx} = -\frac{9}{40} = -0.225 \quad \therefore$ land is sloping downwards.

This means the top of the hill is between $x = \frac{1}{2}$ and $x = 1\frac{1}{2}$.

c The deepest point of the lake occurs when the slope of the land is 0, which is when $\frac{dy}{dx} = 0$

$\therefore \frac{1}{10}(3x^2 - 10x + 6) = 0$

$\therefore 3x^2 - 10x + 6 = 0$

$\therefore x = \frac{10 \pm \sqrt{100 - 72}}{6} = \frac{5 \pm \sqrt{7}}{3}$

but it must be the value between 2 and 3 km, so $x = \frac{5 + \sqrt{7}}{3} \approx 2.55$ km from the sea

The depth at this point is $y(2.549) \approx \frac{1}{10}(2.549)(0.549)(-0.451)$

≈ -0.06311 km

≈ 63.1 m

9 a $\frac{dP}{dt} = aP \left(1 - \frac{P}{b}\right) - \left(\frac{c}{100}\right)P$ and when $\frac{dP}{dt} = 0$, the rate of change of population is zero, so the population is not changing and is stable.

b If $a = 0.06$, $b = 24\,000$, $c = 5$ then

$\frac{dP}{dt} = 0.06P \left(1 - \frac{P}{24\,000}\right) - \frac{5}{100}P$

$= 0.06P - 0.05P - \frac{0.06P^2}{24\,000}$

$= P \left(0.01 - \frac{P}{400\,000}\right)$

Now for a stable population, $\frac{dP}{dt} = 0$

$\therefore P = 0 \quad \text{or} \quad \frac{P}{400\,000} = 0.01$

$\therefore P = 0 \quad \text{or} \quad 4000$

$\therefore$ the stable population is 4000 fish.

c If the harvest rate is 4%, then $\frac{dP}{dt} = 0.06P \left(1 - \frac{P}{24\,000}\right) - \frac{4}{100}P = P \left(0.02 - \frac{0.06P}{24\,000}\right)$

For a stable population, $\frac{dP}{dt} = 0$ and so $0 = P \left(0.02 - \frac{0.06P}{24\,000}\right)$

$$\therefore P = 0 \quad \text{or} \quad \frac{0.06P}{24\,000} = 0.02$$

$$\therefore P = 0 \quad \text{or} \quad \frac{0.02 \times 24\,000}{0.06}$$

$$\therefore P = 0 \quad \text{or} \quad 8000$$

$\therefore$ the stable population is 8000 fish.

10 a $W = 20e^{-kt}$ so when $t = 50$ hours, $W = 10$ g

$$\therefore 20e^{-50k} = 10$$

$$\therefore e^{-50k} = \frac{1}{2}$$

$$\therefore -50k = \ln \frac{1}{2} = -\ln 2 \quad \therefore k = \frac{1}{50} \ln 2 \approx 0.0139$$

b i When $t = 0$,

$$\begin{aligned} W &= 20e^0 \\ &= 20 \text{ g} \end{aligned}$$

ii When $t = 24$,

$$\begin{aligned} W &= 20e^{-24k} \\ &= 20e^{-24 \frac{\ln 2}{50}} \\ &\approx 14.3 \text{ g} \end{aligned}$$

iii When $t = 1$ week

$$\begin{aligned} &= 7 \times 24 \text{ hours} \\ &= 168 \text{ hours} \end{aligned}$$

$$\begin{aligned} W &= 20e^{-168 \frac{\ln 2}{50}} \\ &\approx 1.95 \text{ g} \end{aligned}$$

c When $W = 1$ g, $20e^{-\frac{\ln 2}{50} \times t} = 1$

$$\therefore e^{-\frac{\ln 2}{50} \times t} = 0.05$$

$$\therefore -\frac{\ln 2}{50} \times t = \ln 0.05$$

$$\therefore t = \frac{-50 \ln 0.05}{\ln 2} = 216.096\,404\,7$$

≈ 216 hours or 9 days and 6 minutes

d $\frac{dW}{dt}$

$$= 20e^{-kt}(-k)$$

$$\begin{aligned} \frac{dW}{dt} &= \left(\frac{-20 \ln 2}{50}\right) e^{-2 \ln 2} \\ &\approx -0.0693 \text{ gh}^{-1} \end{aligned}$$

ii When $t = 1000$ hours,

$$\therefore 20 = 5 + 95e^{-15k}$$

$$\therefore 15 = 95e^{-15k}$$

$$\therefore e^{15k} = \frac{95}{15}$$

$$\therefore 15k = \ln\left(\frac{19}{3}\right)$$

$$\therefore k = \frac{1}{15} \ln\left(\frac{19}{3}\right) \approx 0.123$$

b When $t = 0$,

$$\begin{aligned} T &= 5 + 95e^0 \\ &= 5 + 95 \\ &= 100^\circ\text{C} \end{aligned}$$

c $\frac{dT}{dt} = 0 + 95e^{-kt}(-k)$

$$= -(95e^{-kt})k$$

$$= c(T - 5) \quad \text{where } c = -k$$

$$\therefore c \approx -0.123$$

d $\frac{dT}{dt} = -95e^{-kt} \times k \approx -11.6902e^{-0.1231t}$

i When $t = 0$, $\frac{dT}{dt} \approx -11.69$, so the temperature is decreasing at $11.7^\circ\text{C min}^{-1}$.

ii When $t = 10$, $\frac{dT}{dt} \approx -11.6902e^{-1.231} \approx -3.415$,

so the temperature is decreasing at $3.42^\circ\text{C min}^{-1}$.

iii When $t = 20$, $\frac{dT}{dt} \approx -11.6902e^{-2.461} \approx -0.998$,

so the temperature is decreasing at $0.998^\circ\text{C min}^{-1}$.

12 $H(t) = 20 \ln(3t + 2) + 30$ cm, $t \geq 0$

a The shrubs were planted when $t = 0$. $H(0) = 20 \ln(2) + 30 \approx 43.9$ cm

b When $H = 1$ m = 100 cm,
 $20 \ln(3t + 2) + 30 = 100$
 $\therefore 20 \ln(3t + 2) = 70$
 $\therefore \ln(3t + 2) = 3.5$
 $\therefore 3t + 2 = e^{3.5}$
 $\therefore 3t = e^{3.5} - 2$
 $\therefore t = \frac{e^{3.5} - 2}{3}$ years
 $\therefore t \approx 10.4$ years

c $\frac{dH}{dt} = 20 \times \frac{3}{(3t + 2)} = \frac{60}{3t + 2}$ cm year⁻¹

i When $t = 3$, $\frac{dH}{dt} = \frac{60}{11} \approx 5.4545$

$\therefore$ it is growing at 5.45 cm year⁻¹

ii When $t = 10$, $\frac{dH}{dt} = \frac{60}{32} = 1.875$

$\therefore$ it is growing at 1.88 cm year⁻¹

13 **a** $A = s(1 - e^{-kt})$, $t \geq 0$

When $t = 0$, $A = s(1 - e^0)$
 $= s(1 - 1) = 0$

b **i** When $t = 3$, $A = 5$, and $s = 10$,
 $5 = 10(1 - e^{-3k})$
 $\therefore 0.5 = 1 - e^{-3k}$
 $\therefore e^{-3k} = 0.5$
 $\therefore e^{3k} = 2$
 $\therefore 3k = \ln 2$
 $\therefore k = \frac{\ln 2}{3} \approx 0.231$

 $\therefore A - s = -se^{-kt}$

Now, $\frac{dA}{dt} = ske^{-kt}$
 $= k(se^{-kt})$
 $= -k(-se^{-kt})$
 $= -k(A - s)$
 $\therefore \frac{dA}{dt} \propto (A - s)$

ii $\frac{dA}{dt} = ske^{-kt}$

$\therefore$ when $t = 5$ and $s = 10$,

$\frac{dA}{dt} = 10 \left(\frac{1}{3} \ln 2 \right) \left(e^{-\frac{5}{3} \ln 2} \right)$
 ≈ 0.728 litres per hour

14 **a** When $t = 0$,

$B(0) = \frac{C}{1 + 0.5e^0} = \frac{C}{1.5} = \frac{2C}{3}$ bees

b When $t = 1$, $B(1) = \frac{C}{1 + 0.5e^{-1.73}}$
 $\approx \frac{C}{1.089} \approx 0.919C$

$\therefore$ % increase = $\left(\frac{0.919C - \frac{2}{3}C}{\frac{2}{3}C} \right) \times 100\%$
 $\approx 37.8\%$ increase

c As $t \rightarrow \infty$, $e^{-1.73t} \rightarrow 0$, and so
 $B(t)$ approaches $\frac{C}{1 + 0} = C$
 $\therefore$ the population is limited to C bees.

d $B(2) = \frac{C}{1 + 0.5e^{-1.73 \times 2}} = 4500$
 $\therefore \frac{C}{1.016} = 4500$
 $\therefore C \approx 4570.7$

$\therefore$ from **a**, initial population = $\frac{2C}{3}$
 ≈ 3047 bees

$$\begin{aligned}

Since $C > 0$, $B'(t) > 0$ for all t

$\therefore B(t)$ is increasing over time.

a When $t = 8$, $\frac{dd}{dt} = -3.4476 \sin(0.507 \times 8)$
 ≈ 2.73

$\therefore$ the rate of change in the depth of water is 2.73 m per hour.

$\therefore$ the tide is rising.

$$\begin{aligned} V'(0.01) &= 34\,000\pi \times \cos \pi \\ &= -34\,000\pi \text{ units per second} \end{aligned}$$

b When $V(t)$ is a maximum,
 $V'(t)$ must be 0 units per second.

18 a The distance from $A(-x, 0)$ to $P(\cos t, \sin t)$ is fixed at 2 m.

$$\cos t = \frac{OQ}{1} = OQ$$

Using technology, $x \approx 103.74$ or $x \approx 67.30$

x	50	67.30	103.74	150
$C(x)$	531.65	546.73	529.80	680.95

$\therefore$ the maximum hourly cost is \$680.95 when 150 hinges are made per hour. The minimum hourly cost is \$529.80 when 104 hinges are made per hour.

8 $C(x) = 4 \ln x + \left(\frac{30-x}{10}\right)^2, \quad x \geq 10$

$$\therefore C'(x) = \frac{4}{x} + 2 \left(\frac{30-x}{10}\right) \left(-\frac{1}{10}\right)$$
$$= \frac{4}{x} - \frac{30-x}{50}$$
$$= \frac{200 - x(30-x)}{50x}$$
$$= \frac{200 - 30x + x^2}{50x}$$
$$= \frac{(x-10)(x-20)}{50x}$$

$\therefore$ the minimum cost occurs when $x = 20$ or when 20 kettles per day are produced.

9 a Inner length of box = $2x$ cm

c From **b**, $h = \frac{100}{x^2}$

Area of inner surface is

$$\begin{aligned} A(x) &= 2(2x \times x) + 2(2x \times h) \\ &\quad + 2(x \times h) \\ &= 4x^2 + 4xh + 2xh \\ &= 4x^2 + 6xh \\ &= 4x^2 + \frac{600}{x} \text{ cm}^2 \end{aligned}$$

e $A(x) = 4x^2 + 600x^{-1}$
 $\therefore A'(x) = 8x - 600x^{-2}$
 $= 8x - \frac{600}{x^2}$
 $\therefore A'(x) = 0$ when $8x = \frac{600}{x^2}$

$$\begin{aligned} \therefore 8x^3 &= 600 \\ \therefore x^3 &= 75 \\ \therefore x &\approx 4.217 \text{ cm} \end{aligned}$$

$$\begin{aligned} A''(x) &= 8 + 1200x^{-3} \\ &= 8 + \frac{1200}{x^3} \end{aligned}$$

$$\therefore A''(x) > 0 \quad \{\text{as } x > 0\}$$

$\therefore$ area is minimised when $x \approx 4.22$ cm

$$\begin{aligned} \therefore A_{\min} &\approx 4(4.217)^2 + \frac{600}{(4.217)} \\ &\approx 213 \text{ cm}^2 \end{aligned}$$

b Volume = 200 cm^3

$$\therefore x \times 2x \times h = 200$$

$$2x^2h = 200$$

$$\therefore x^2h = 100$$

f Height $h \approx \frac{100}{(4.217)^2}$
 ≈ 5.62 cm

10 Let coordinates of D be $(x, 0)$ where $x > 0$.

$\therefore$ the coordinates of C are (x, e^{-x^2}) .

$\therefore$ area ABCD = $2xe^{-x^2}$

$$\begin{aligned} \therefore \frac{dA}{dx} &= 2e^{-x^2} + 2xe^{-x^2}(-2x) \quad \{\text{product rule}\} \\ &= 2e^{-x^2}(1 - 2x^2) \\ &= 2e^{-x^2}(1 + \sqrt{2}x)(1 - \sqrt{2}x) \end{aligned}$$

$\frac{dA}{dx}$ has sign diagram:

$\therefore$ the area is a maximum when $x = \frac{1}{\sqrt{2}}$
 and so C is $\left(\frac{1}{\sqrt{2}}, e^{-\frac{1}{2}}\right)$.

11 a Volume of can = $\pi r^2 h$

$$\therefore 1000 = \pi r^2 h \quad (\text{in cm})$$

$$\therefore h = \frac{1000}{\pi r^2} \text{ cm}$$

b Opening the can up we get:

$$\begin{aligned} \therefore A(r) &= \pi r^2 + \pi r^2 + 2\pi r h \\ &= 2\pi r^2 + 2\pi r h \\ &= 2\pi r^2 + \frac{2000}{r} \text{ cm}^2 \end{aligned}$$

d $A(r) = 2\pi r^2 + 2000r^{-1}$
 $A'(r) = 4\pi r - 2000r^{-2} = 4\pi r - \frac{2000}{r^2}$
So, $A'(r) = 0$ when $4\pi r = \frac{2000}{r^2}$
 $r^3 = \frac{2000}{4\pi}$
 $r = \sqrt[3]{\frac{500}{\pi}} \approx 5.42 \text{ cm}$

$$A''(r) = 4\pi + 4000r^{-3} = 4\pi + \frac{4000}{r^3}$$

and as $r > 0$, $A''(r) > 0$
 $\therefore$ area is a minimum when $r \approx 5.42 \text{ cm}$
and $h = \frac{1000}{\pi r^2} \approx 10.8 \text{ cm}$
 $A_{\min} = 2\pi r^2 + 2\pi r h \approx 554 \text{ cm}^2$

a Using the cosine rule in $\triangle BCO$,
 $BC^2 = 10^2 + 10^2 - 2 \times 10 \times 10 \cos \theta$
 $\therefore BC = \sqrt{200 - 200 \cos \theta}$
 $\therefore XY = \sqrt{200 - 200 \cos \theta}$ also
Now $BY^2 = BX^2 + XY^2$ {Pythagoras}
 $\therefore 400 = BX^2 + (200 - 200 \cos \theta)$
 $\therefore BX^2 = 200 + 200 \cos \theta$
 $\therefore BX = \sqrt{200 + 200 \cos \theta}$

The shaded area is equal to the area of the sector plus $\frac{3}{4}$ of the area of BCYX.

$$\begin{aligned} \therefore A &= \frac{1}{2} (10)^2 \theta + \frac{3}{4} (BX \times BC) \\ &= 50\theta + \frac{3}{4} \sqrt{200 + 200 \cos \theta} \sqrt{200 - 200 \cos \theta} \\ &= 50\theta + \frac{3}{4} \times 200 \sqrt{1 + \cos \theta} \sqrt{1 - \cos \theta} \\ &= 50\theta + 150 \sqrt{1 - \cos^2 \theta} \\ &= 50\theta + 150 \sin \theta \\ &= 50(\theta + 3 \sin \theta) \text{ as required} \end{aligned}$$

b $\frac{dA}{d\theta} = 50 + 150 \cos \theta = 50(1 + 3 \cos \theta)$

which is zero when $\cos \theta = -\frac{1}{3}$
 $\therefore \theta \approx 1.91$

Since $0 < \theta < \pi$, A is maximised when $\theta \approx 1.91$.

When $\theta \approx 1.91$, $A \approx 237$ $\therefore$ the maximum area is 237 cm^2 .

13

The volume of the container is
 $V = \text{length} \times \text{width} \times \text{depth}$
 $= x(36 - 2x)(36 - 2x)$
 $\therefore V = x(36 - 2x)^2 \text{ cm}^3$

- b** The container will have the greatest capacity when $V(x)$ is maximised.

Using the product rule,

$$\begin{aligned} V'(x) &= (36 - 2x)^2 - 4x(36 - 2x) \\ &= (36 - 2x)[(36 - 2x) - 4x] \\ &= (36 - 2x)(36 - 6x) \end{aligned}$$

$$\therefore V'(x) = 0 \text{ when } x = 6 \text{ or } x = 18$$

Sign diagram of $V'(x)$ is:

$\therefore$ the volume is maximised when $x = 6 \text{ cm}$ $\{0 \leq x < 18\}$

So, $6 \text{ cm} \times 6 \text{ cm}$ squares should be cut out to maximise the capacity.

- c** The metal sheet is $a \text{ cm}$ by $a \text{ cm}$ and squares which are $x \text{ cm}$ by $x \text{ cm}$ are cut out.

$$\begin{aligned} V &= \text{length} \times \text{width} \times \text{depth} \\ &= (a - 2x) \times (a - 2x) \times x \end{aligned}$$

$$\therefore V = x(a - 2x)^2$$

$$\begin{aligned} \text{Now } V'(x) &= (a - 2x)^2 - 4x(a - 2x) \\ &= (a - 2x)[(a - 2x) - 4x] \\ &= (a - 2x)(a - 6x) \end{aligned}$$

$$\therefore V'(x) = 0 \text{ when } x = \frac{a}{2} \text{ or } x = \frac{a}{6}$$

$$\text{But } a - 2x > 0 \quad \therefore x < \frac{a}{2}$$

$$\text{So } x = \frac{a}{6} \text{ is the only value in } 0 < x < \frac{a}{2}$$

with $V'(x) = 0$.

Second derivative test:

$$\begin{aligned} V''(x) &= -2(a - 6x) + (a - 2x)(-6) \\ &= -2a + 12x - 6a + 12x \\ &= 24x - 8a \end{aligned}$$

$$\therefore V''\left(\frac{a}{6}\right) = 4a - 8a = -4 \text{ which is } < 0$$

$\therefore$ the shape is  and we have a local maximum.

$$\therefore \text{ the volume is maximised when } x = \frac{a}{6}.$$

14 a $P = 2\pi r + 2l$
 $\therefore 400 = 2\pi(x) + 2l$
 $\therefore 200 = \pi x + l$
 $\therefore l = 200 - \pi x$

Now clearly $x \geq 0$ and $l \geq 0$

$$\therefore \pi x \leq 200$$

$$\therefore x \leq \frac{200}{\pi}$$

$$\begin{aligned} \text{So, } 0 &\leq x \leq \frac{200}{\pi} \\ \text{or } 0 &\leq x \leq 63.7 \end{aligned}$$

b Area of shaded rectangle $A = 2xl \text{ m}^2$

$$\begin{aligned} \therefore A &= 2x(200 - \pi x) \text{ m}^2 \\ &= 400x - 2\pi x^2 \text{ m}^2 \end{aligned}$$

$$\text{Now } \frac{dA}{dx} = 400 - 4\pi x$$

which is 0 when $4\pi x = 400$

$$\therefore x = \frac{100}{\pi} \approx 31.83 \text{ m}$$

$$\begin{aligned} \text{and so } l &= 200 - \pi\left(\frac{100}{\pi}\right) \\ &= 100 \text{ m} \end{aligned}$$

So, the maximum area of the rectangle is

$$2 \times \frac{100}{\pi} \times 100 \approx 6366 \text{ m}^2.$$

15 $P(t) = \frac{50\,000}{1 + 1000e^{-0.5t}}, \quad 0 \leq t \leq 25$
 $= 50\,000(1 + 1000e^{-0.5t})^{-1}$
 $\therefore P'(t) = -50\,000(1 + 1000e^{-0.5t})^{-2}(-500e^{-0.5t})$
 $= 2.5 \times 10^7 e^{-0.5t}(1 + 1000e^{-0.5t})^{-2}$

The wasp population is growing the fastest when $\frac{dP}{dt}$ is a maximum.

Using technology, the graph of $P'(t)$ can be drawn and the maximum obtained.

The maximum occurs when $t \approx 13.8$ weeks.

$$\begin{aligned}
 16 \quad E(t) &= 750te^{-1.5t} \\
 \therefore E'(t) &= 750e^{-1.5t} + 750t \times -1.5e^{-1.5t} \\
 &= 750e^{-1.5t} - 1125te^{-1.5t} \\
 &= e^{-1.5t}(750 - 1125t)
 \end{aligned}$$

Now $E'(t) = 0$ when $750 - 1125t = 0$ {since $e^{-1.5t} > 0$ for all $t \in \mathbb{R}$ }

$$\therefore 1125t = 750$$

$$\therefore t = \frac{2}{3} \text{ hours (or 40 minutes)}$$

Sign diagram for $E'(t)$:

$$\therefore \frac{d[D(x)]^2}{dx} = 4x - 48$$

$$\therefore \frac{d[D(x)]^2}{dx} = 0 \text{ when } x = 12$$

The total intensity $I = \frac{40k}{x^2} + \frac{5k}{(6-x)^2}$
 $= k[40x^{-2} + 5(6-x)^{-2}]$

$$\therefore \frac{dI}{dx} = k[-80x^{-3} - 10(6-x)^{-3}(-1)]$$

$$= k \left[\frac{-80}{x^3} + \frac{10}{(6-x)^3} \right]$$

$$\therefore \frac{dI}{dx} = 0 \text{ when } \frac{80}{x^3} = \frac{10}{(6-x)^3}$$

$$\therefore 8(6-x)^3 = x^3$$

$$\therefore 2(6-x) = x \quad \{\text{finding cube roots}\}$$

$$\therefore 12 - 2x = x$$

$$\therefore x = 4$$

$\therefore$ the darkest point occurs 4 m from the 40 cp lamp.

25

$$\cos \alpha = \frac{3}{a} \quad \text{and} \quad \sin \alpha = \frac{4}{b}$$

$$\therefore a = \frac{3}{\cos \alpha} \quad \text{and} \quad b = \frac{4}{\sin \alpha}$$

Now $L = a + b$

$$\therefore L = \frac{3}{\cos \alpha} + \frac{4}{\sin \alpha}$$

$$= 3(\cos \alpha)^{-1} + 4(\sin \alpha)^{-1}$$

$$\therefore \frac{dL}{d\alpha} = -3(\cos \alpha)^{-2} \times (-\sin \alpha) - 4(\sin \alpha)^{-2} \times \cos \alpha$$

$$= \frac{3 \sin \alpha}{\cos^2 \alpha} - \frac{4 \cos \alpha}{\sin^2 \alpha}$$

$$= \frac{3 \sin^3 \alpha - 4 \cos^3 \alpha}{\cos^2 \alpha \sin^2 \alpha}$$

$$\therefore \frac{dL}{d\alpha} = 0$$

when $3 \sin^3 \alpha - 4 \cos^3 \alpha = 0$

$$\therefore 3 \sin^3 \alpha = 4 \cos^3 \alpha$$

$$\therefore \tan^3 \alpha = \frac{4}{3}$$

$$\therefore \tan \alpha = \sqrt[3]{\frac{4}{3}}$$

$$\therefore \alpha \approx 47.74^\circ$$

$\therefore L$ is minimised when $\alpha \approx 47.74^\circ$ and $L = \frac{3}{\cos \alpha} + \frac{4}{\sin \alpha} \approx 9.87$ m

So, the maximum possible length of the X-ray screen is 9.87 m.

26 a $\tan \theta = \frac{2}{AX}$ and $\sin \theta = \frac{2}{BX}$

$$\therefore AX = \frac{2}{\tan \theta} = \frac{2 \cos \theta}{\sin \theta} \quad \text{and} \quad BX = \frac{2}{\sin \theta}$$

From the similar $\triangle$ s, $\frac{L}{BX} = \frac{AX + 2}{AX} = 1 + \frac{2}{AX}$

$$\therefore L = BX + \frac{2BX}{AX}$$

$$= \frac{2}{\sin \theta} + \frac{2 \left(\frac{2}{\sin \theta} \right)}{\left(\frac{2 \cos \theta}{\sin \theta} \right)}$$

$$= \frac{2}{\sin \theta} + 2 \left(\frac{2}{\sin \theta} \right) \left(\frac{\sin \theta}{2 \cos \theta} \right)$$

$$= 2 \sec \theta + 2 \csc \theta, \text{ as required}$$

b Now $L = 2 \sec \theta + 2 \csc \theta$

$$\begin{aligned} \therefore \frac{dL}{d\theta} &= 2 \sec \theta \tan \theta - 2 \csc \theta \cot \theta \\ &= \frac{2 \sin \theta}{\cos^2 \theta} - \frac{2 \cos \theta}{\sin^2 \theta} \\ &= \frac{2 \sin^3 \theta - 2 \cos^3 \theta}{\sin^2 \theta \cos^2 \theta} \end{aligned}$$

c Now $\frac{dL}{d\theta} = 0$ when $2 \sin^3 \theta - 2 \cos^3 \theta = 0$

$$\begin{aligned} \therefore 2 \sin^3 \theta &= 2 \cos^3 \theta \\ \therefore \tan^3 \theta &= 1 \\ \therefore \tan \theta &= 1 \\ \therefore \text{since } 0 < \theta < 90^\circ, \quad \theta &= 45^\circ \end{aligned}$$

Sign diagram of $\frac{dL}{d\theta}$ is:

$\therefore$ the ladder is shortest when $\theta = 45^\circ$
 $\therefore \sec \theta = \sqrt{2}$ and $\csc \theta = \sqrt{2}$
 $\therefore L_{\min} = 2\sqrt{2} + 2\sqrt{2} = 4\sqrt{2} \text{ m}$

27

Now $\alpha_1 = \alpha_2$ and $\beta_1 = \beta_2$ {alternate angles}
 $\therefore \theta = \alpha + \beta$

Let $AX = x \text{ m}$

$\therefore XB = (4 - x) \text{ m}$

$\therefore \tan \alpha = \frac{x}{5}$ and $\tan \beta = \frac{4 - x}{3}$

Now $\tan \theta = \tan(\alpha + \beta)$

$$\begin{aligned} &= \frac{\tan \alpha + \tan \beta}{1 - \tan \alpha \tan \beta} \\ &= \frac{\frac{x}{5} + \frac{4 - x}{3}}{1 - \frac{x}{5} \left(\frac{4 - x}{3} \right)} \times \frac{15}{15} \\ &= \frac{3x + 20 - 5x}{15 - x(4 - x)} = \frac{20 - 2x}{x^2 - 4x + 15} \end{aligned}$$

Differentiating both sides with respect to x

$$\begin{aligned} \sec^2 \theta \frac{d\theta}{dx} &= \frac{-2(x^2 - 4x + 15) - (20 - 2x)(2x - 4)}{(x^2 - 4x + 15)^2} \quad \{\text{chain and quotient rules}\} \\ &= \frac{-2x^2 + 8x - 30 - 40x + 80 + 4x^2 - 8x}{(x^2 - 4x + 15)^2} \\ &= \frac{2x^2 - 40x + 50}{(x^2 - 4x + 15)^2} \\ \therefore \frac{d\theta}{dx} &= 2 \cos^2 \theta \frac{x^2 - 20x + 25}{(x^2 - 4x + 15)^2} \end{aligned}$$

Now by inspection, $\theta < 90^\circ$, so $\frac{d\theta}{dx} = 0$ when $x^2 - 20x + 25 = 0$

$\therefore x \approx 1.3397$ or $x \approx 18.660$ (where 18.660 is not physically possible)

$\therefore x \approx 1.34 \text{ m}$ from A

Sign diagram for $\frac{d\theta}{dx}$ is:

$\therefore \theta$ is a maximum when $x \approx 1.34 \text{ m}$ from A.

28

$$\frac{PX}{2} = \cos \theta \quad \therefore PQ = 2PX = 4 \cos \theta$$

$\therefore$ the time taken to row from P to Q is $\frac{4 \cos \theta}{3}$ hours

Now $\phi = 2\theta$ {angle at the centre}

But, arc length $QR_{\text{arc}} = 2\phi$

$$\therefore QR_{\text{arc}} = 4\theta$$

and the time taken to walk from Q to R is $\frac{4\theta}{5}$

$\therefore$ the total time from P to R, $T = \frac{4}{3} \cos \theta + \frac{4\theta}{5}$

$$\therefore \frac{dT}{d\theta} = -\frac{4}{3} \sin \theta + \frac{4}{5}$$

$$\therefore \frac{dT}{d\theta} = 0 \quad \text{when} \quad -\frac{4}{3} \sin \theta = -\frac{4}{5}$$

$$\therefore \sin \theta = \frac{3}{5}$$

$$\therefore \theta \approx 0.6435 \text{ radians}$$

$$\therefore \theta \approx 36.87^\circ$$

So the maximum time occurs when $\theta \approx 36.9^\circ$

and the maximum time is $\frac{4}{3} \cos 0.6435 + \frac{4}{5} \times 0.6435 \approx 1.581$ hours

$\approx 1 \text{ hour } 34 \text{ min } 53 \text{ s}$

and the sign diagram of $\frac{dT}{d\theta}$ is:

29 a $\tan \alpha = \frac{2}{x}$ and $\tan(\alpha + \theta) = \frac{3}{x}$

b Now $\theta = (\alpha + \theta) - \alpha = \arctan\left(\frac{3}{x}\right) - \arctan\left(\frac{2}{x}\right)$

c $\frac{d\theta}{dx} = \left(-\frac{3}{x^2}\right) \times \frac{1}{1 + \left(\frac{3}{x}\right)^2} - \left(-\frac{2}{x^2}\right) \times \frac{1}{1 + \left(\frac{2}{x}\right)^2}$

$$= -\frac{3}{x^2 + 9} + \frac{2}{x^2 + 4}$$

$$= \frac{2}{x^2 + 4} - \frac{3}{x^2 + 9} \quad \text{as required}$$

So, $\frac{d\theta}{dx} = 0$ when $2(x^2 + 9) - 3(x^2 + 4) = 0$

$$\therefore 2x^2 + 18 - 3x^2 - 12 = 0$$

$$\therefore x^2 = 6$$

$$\therefore x = \sqrt{6} \quad \{x > 0\}$$

and $\frac{d\theta}{dx}$ has sign diagram:

d The maximum viewing angle occurs when $x = \sqrt{6}$, which is when Sonia is $\sqrt{6}$ m from the wall.

30 Suppose P has coordinates $(x, 8)$

$$\begin{aligned} \therefore CP &= \sqrt{(x-3)^2 + (8-11)^2} \\ &= \sqrt{x^2 - 6x + 9 + 9} \\ &= \sqrt{x^2 - 6x + 18} \end{aligned}$$

$$\begin{aligned} AP &= \sqrt{(x-1)^2 + (8-2)^2} \\ &= \sqrt{x^2 - 2x + 1 + 36} \\ &= \sqrt{x^2 - 2x + 37} \end{aligned}$$

$$\begin{aligned} BP &= \sqrt{(x-7)^2 + (8-3)^2} \\ &= \sqrt{x^2 - 14x + 49 + 25} \\ &= \sqrt{x^2 - 14x + 74} \end{aligned}$$

$$\therefore \text{the length of pipeline } L = \sqrt{x^2 - 6x + 18} + \sqrt{x^2 - 2x + 37} + \sqrt{x^2 - 14x + 74}$$

We use technology to graph L and to find its minimum. This occurs when $x \approx 3.54366$, and $L \approx 15.6$

$\therefore$ P is at $(3.54, 8)$ and the shortest total length of pipe required is 15.6 km.

31 Suppose $PN = x$ m

$\therefore$ length of cable = $PA + PB + PC$

$$\therefore L = 8 - x + \sqrt{x^2 + 16} + \sqrt{x^2 + 25}$$

Using technology we graph and find the minimum value of the function.

$\therefore$ the minimum length occurs when $x \approx 2.57798$

$\therefore$ P should be ≈ 2.58 m from N.

32 $r^2 + h^2 = s^2$ {Pythagoras}

$$\therefore h^2 = s^2 - r^2$$

$$\therefore h = \sqrt{s^2 - r^2}$$

$$\text{But } V = \frac{1}{3}\pi r^2 h$$

$$\therefore V = \frac{1}{3}\pi r^2 \sqrt{s^2 - r^2}$$

$$\therefore V^2 = \frac{\pi^2}{9} r^4 (s^2 - r^2)$$

$$= \frac{\pi^2}{9} (r^4 s^2 - r^6)$$

$$\therefore \frac{d(V^2)}{dr} = \frac{\pi^2}{9} (4r^3 s^2 - 6r^5)$$

$$= \frac{\pi^2}{9} 2r^3 (2s^2 - 3r^2)$$

$$\frac{d(V^2)}{dr} = 0 \text{ when } 2s^2 - 3r^2 = 0 \quad \{\text{as } r > 0\}$$

$$\therefore 2s^2 = 3r^2$$

$$\therefore \frac{s^2}{r^2} = \frac{3}{2}$$

$$\therefore \frac{s}{r} = \sqrt{\frac{3}{2}}$$

$$\therefore s : r = \sqrt{\frac{3}{2}} : 1$$

Sign diagram of $\frac{d(V^2)}{dr}$ is:

$\therefore V$ is a maximum when $s : r = \sqrt{\frac{3}{2}} : 1 = \sqrt{3} : \sqrt{2}$

33 a $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

$$\therefore x^2 b^2 + y^2 a^2 = a^2 b^2 \quad \{\times \text{ by } a^2 b^2\}$$

$$\therefore a^2 y^2 = a^2 b^2 - x^2 b^2$$

$$\therefore y^2 = \frac{a^2 b^2 - x^2 b^2}{a^2}$$

$$\therefore y = \pm \sqrt{\frac{a^2 b^2 - x^2 b^2}{a^2}}$$

Since A lies in Q_1 , $y > 0$

$$\therefore y = \sqrt{\left(\frac{b^2}{a^2}\right)(a^2 - x^2)}$$

$$\therefore y = \frac{b}{a} \sqrt{a^2 - x^2}$$

b The seating area is $A = 2x \times 2y$
 $= 4xy$

$$= 4x \left(\frac{b}{a} \sqrt{a^2 - x^2}\right)$$

$$\therefore A(x) = \frac{4bx}{a} \sqrt{a^2 - x^2} \text{ as required}$$

$$\therefore A^2 = \frac{16b^2 x^2}{a^2} (a^2 - x^2)$$

$$= \frac{16b^2}{a^2} (a^2 x^2 - x^4)$$

c $\frac{d(A^2)}{dx} = \frac{16b^2}{a^2} (2a^2 x - 4x^3)$

which is 0 when

$$2a^2 x - 4x^3 = 0$$

$$\therefore 2x(a^2 - 2x^2) = 0$$

$$\therefore 2x^2 = a^2 \quad \{\text{as } x > 0\}$$

$$\therefore x = \pm \frac{a}{\sqrt{2}}$$

$$\therefore x = \frac{a}{\sqrt{2}} \quad \{\text{as } x \text{ is in } Q_1\}$$

Sign diagram of $\frac{d(A^2)}{dx}$ is:

$\therefore$ maximum area occurs when $x = \frac{a}{\sqrt{2}}$

$$\begin{aligned} \text{Max. area} &= \frac{4b}{a} \times \frac{a}{\sqrt{2}} \sqrt{a^2 - \left(\frac{a}{\sqrt{2}}\right)^2} \\ &= \frac{4b}{\sqrt{2}} \times \sqrt{\frac{a^2}{2}} \\ &= \frac{4b}{\sqrt{2}} \times \frac{a}{\sqrt{2}} = 2ab \end{aligned}$$

$$\mathbf{d} \quad \% \text{ occupied} = \frac{2ab}{\pi ab} \times 100\% = 63.7\%$$

EXERCISE 20D

$$\mathbf{1} \quad ab^3 = 40 \quad \therefore \frac{da}{dt} b^3 + a(3b^2) \frac{db}{dt} = 0$$

$$\text{Particular case: When } a = 5, b = 2, \text{ and } \frac{db}{dt} = +1, \text{ so } 8 \frac{da}{dt} + 5(12)(1) = 0$$

$$\therefore \frac{da}{dt} = -\frac{60}{8} = -7.5$$

$\therefore a$ decreases at 7.5 units per second

2

$$A = LB = 100 \text{ cm}^2 \quad \therefore \frac{dL}{dt} B + L \frac{dB}{dt} = 0$$

Particular case:

$$\text{When a square, } L = B = 10 \text{ cm and } \frac{dL}{dt} = -1$$

$$\therefore 10 \frac{dB}{dt} + 10(-1) = 0$$

$$\therefore \frac{dB}{dt} = 1 \text{ cm min}^{-1}$$

$\therefore$ the breadth is increasing at 1 cm min^{-1} .

$$\mathbf{3} \quad A = \pi r^2 \quad \therefore \frac{dA}{dt} = 2\pi r \frac{dr}{dt} = 2\pi r \quad \{\text{since } \frac{dr}{dt} = 1 \text{ m s}^{-1}\}$$

Particular cases:

$$\mathbf{a} \quad \text{When } t = 2 \text{ and } r = 2, \quad \frac{dA}{dt} = 2\pi(2) = 4\pi \text{ m}^2 \text{ per second}$$

$$\mathbf{b} \quad \text{When } t = 4 \text{ and } r = 4, \quad \frac{dA}{dt} = 2\pi(4) = 8\pi \text{ m}^2 \text{ per second}$$

$$\mathbf{4} \quad V = \frac{4}{3}\pi r^3 \quad \therefore \frac{dV}{dt} = 4\pi r^2 \frac{dr}{dt} = 6\pi \text{ m}^3 \text{ min}^{-1}$$

$$\therefore \frac{dr}{dt} = \frac{6\pi}{4\pi r^2} = \frac{3}{2r^2} \text{ m min}^{-1}$$

$$\text{Now } A = 4\pi r^2$$

$$\therefore \frac{dA}{dt} = 8\pi r \frac{dr}{dt} = 8\pi r \times \frac{3}{2r^2}$$

$$\text{Particular case: When } r = 2, \quad \frac{dA}{dt} = \frac{8\pi \times 2 \times 3}{2 \times 4} \text{ m}^2 \text{ min}^{-1} = 6\pi \text{ m}^2 \text{ min}^{-1}$$

$\therefore$ the surface area is increasing at $6\pi \text{ m}^2$ per minute.

$$\mathbf{5} \quad pV^{\frac{3}{2}} = 400 \quad \therefore \frac{dp}{dt} V^{\frac{3}{2}} + \frac{3}{2}pV^{\frac{1}{2}} \frac{dV}{dt} = 0$$

$$\text{Particular case: When } p = 50 \text{ Nm}^{-2}, \quad V^{\frac{3}{2}} = 8 \text{ and so } V = 4$$

$$\therefore 3(8) + \frac{3}{2}(50)(2) \frac{dV}{dt} = 0 \quad \{\text{as } \frac{dp}{dt} = +3 \text{ Nm}^{-2}\}$$

$$\therefore \frac{dV}{dt} = -\frac{24}{150} \text{ m}^3 \text{ min}^{-1}$$

$\therefore$ the volume is decreasing at 0.16 m^3 per minute.

6 $V = \frac{1}{3}\pi r^2 h$ and $r = 3h$

$\therefore V = \frac{1}{3}\pi(3h)^2 h = 3\pi h^3 \dots (*)$

Particular case: After 1 min, the volume $V = 3\pi(20)^3 \text{ cm}^3 = 24\,000\pi \text{ cm}^3$

$\therefore \frac{dV}{dt} = 24\,000\pi \text{ cm}^3 \text{ min}^{-1}$

But $\frac{dV}{dt} = 9\pi h^2 \frac{dh}{dt}$ {from (*)}

$\therefore$ when $h = 20$, $24\,000\pi = 9\pi \times (20^2) \times \frac{dh}{dt}$

$\therefore \frac{dh}{dt} = \frac{24\,000\pi}{400 \times 9\pi} = \frac{20}{3} \text{ cm min}^{-1}$

$\therefore$ the height is rising at $\frac{20}{3}$ cm per minute.

7

$\theta = 30^\circ \therefore \frac{x}{h} = \tan 30^\circ$

$\therefore x = h \tan 30^\circ = \frac{h}{\sqrt{3}}$

$\therefore V = \frac{h}{\sqrt{3}} \times h \times 600 = 200\sqrt{3}h^2 \text{ cm}^3$

$\therefore \frac{dV}{dt} = 400\sqrt{3}h \frac{dh}{dt}$

Particular case: When $h = 20$, $-100\,000 = 400\sqrt{3}(20) \frac{dh}{dt}$ $\left\{ \frac{dV}{dt} = -0.1 \text{ m}^3 = -100\,000 \text{ cm}^3 \right\}$

$\therefore \frac{dh}{dt} = \frac{-100\,000}{400\sqrt{3} \times 20} = -\frac{25}{6}\sqrt{3} \text{ cm min}^{-1}$

$\therefore$ the water level is falling at $\frac{25\sqrt{3}}{6} \approx 7.22$ cm per minute

8 Let P_1 in the diagram be the faster jet and P_2 be the slower jet. Let y m be the distance that P_2 is ahead of P_1 , and x m be the distance between them.

Now $x^2 = y^2 + (12\,000)^2$ {Pythagoras}

$\therefore 2x \frac{dx}{dt} = 2y \frac{dy}{dt}$

Particular case:

As P_1 is behind P_2 , it is catching up at a rate of 50 m s^{-1} .

$\therefore \frac{dy}{dt} = -50 \text{ m s}^{-1}$

When $y = 5000$, $x = 13\,000$

$\therefore 26\,000 \times \frac{dx}{dt} = 10\,000 \times (-50)$

$\frac{dx}{dt} = \frac{10}{26} \times (-50) = -\frac{250}{13} \text{ m s}^{-1}$

$\therefore$ their separation is decreasing at $\frac{250}{13} \approx 19.2 \text{ m s}^{-1}$.

9 Let S m be the height of the person's shadow and x m be the person's distance from the building. $\triangle ABC$ and $\triangle AXY$ are similar.

$\therefore \frac{AB}{AX} = \frac{BC}{XY}$

$\therefore \frac{40-x}{40} = \frac{2}{S}$

$\therefore S = \frac{80}{40-x} = 80(40-x)^{-1}$

$$\therefore \frac{dS}{dt} = -80(40-x)^{-2}(-1) \frac{dx}{dt} = \frac{80}{(40-x)^2} \frac{dx}{dt}$$

But $\frac{dx}{dt} = -1 \text{ m s}^{-1}$, so $\frac{dS}{dt} = -\frac{80}{(40-x)^2}$

Particular cases:

a When $x = 20 \text{ m}$, $\frac{dS}{dt} = -\frac{80}{(40-20)^2} = -\frac{80}{400} = -0.2$

$\therefore$ the person's shadow is shortening at 0.2 m s^{-1}

b When $x = 10 \text{ m}$, $\frac{dS}{dt} = -\frac{80}{(40-10)^2} = -\frac{80}{900} = -\frac{8}{90}$

$\therefore$ the person's shadow is shortening at $\frac{8}{90} \text{ m s}^{-1}$

10

$$\cos \theta = \frac{x}{10}$$

$$\therefore -\sin \theta \frac{d\theta}{dt} = \frac{1}{10} \frac{dx}{dt} \quad \{\text{differentiating with respect to } t\}$$

If the length AB increases at 0.1 cm s^{-1} , $\frac{dx}{dt} = 0.1 \text{ cm s}^{-1}$

Particular case: When ABC is isosceles, $\theta = 45^\circ$

$$\therefore \sin \theta = \frac{1}{\sqrt{2}}$$

$$\therefore -\frac{1}{\sqrt{2}} \frac{d\theta}{dt} = \frac{1}{10} \times 0.1$$

$$\therefore \frac{d\theta}{dt} = -\frac{\sqrt{2}}{100} \text{ radians s}^{-1}$$

$\therefore \hat{CAB}$ is decreasing at $\frac{\sqrt{2}}{100}$ radians per second.

11

$$\tan E = \frac{5000}{x} = 5000x^{-1}$$

Differentiating with respect to t ,

$$\sec^2 E \frac{dE}{dt} = -5000x^{-2} \frac{dx}{dt}$$

Now $\frac{dx}{dt} = 200 \text{ m s}^{-1}$,

$$\therefore \frac{1}{\cos^2 E} \frac{dE}{dt} = -5000 \times \frac{1}{x^2} \times 200$$

$$\therefore \frac{dE}{dt} = -1\,000\,000 \times \frac{\cos^2 E}{x^2}$$

Particular cases:

a When $E = 60^\circ$, $\cos E = \frac{1}{2}$
and $\tan E = \sqrt{3} = \frac{5000}{x}$
 $\therefore x = \frac{5000}{\sqrt{3}}$

$$\therefore \frac{dE}{dt} = -1\,000\,000 \times \frac{\left(\frac{1}{2}\right)^2}{\left(\frac{5000}{\sqrt{3}}\right)^2}$$

$$= -0.03$$

$\therefore$ the angle of elevation is decreasing at 0.03 radians per second

b When $E = 30^\circ$, $\cos E = \frac{\sqrt{3}}{2}$
and $\tan E = \frac{1}{\sqrt{3}} = \frac{5000}{x}$
 $\therefore x = 5000\sqrt{3}$

$$\therefore \frac{dE}{dt} = -1\,000\,000 \times \frac{\left(\frac{\sqrt{3}}{2}\right)^2}{(5000\sqrt{3})^2}$$

$$= -0.01$$

$\therefore$ the angle of elevation is decreasing at 0.01 radians per second

12

Let N be the midpoint of [QR] in isosceles triangle QMR.
 $\therefore MN = 10$ cm

Let $QR = x$ cm and let $\widehat{QMR} = \theta$.

$$\text{In triangle MNQ, } \tan\left(\frac{\theta}{2}\right) = \frac{QN}{MN} = \frac{\frac{x}{2}}{10} = \frac{x}{20}$$

$$\therefore \frac{1}{2} \sec^2\left(\frac{\theta}{2}\right) \frac{d\theta}{dt} = \frac{1}{20} \frac{dx}{dt}$$

$$\therefore \frac{d\theta}{dt} = \frac{1}{10} \cos^2\left(\frac{\theta}{2}\right) \frac{dx}{dt}$$

$$\text{where } \frac{dx}{dt} = 2 \text{ cm s}^{-1}$$

Particular case: When $x = 15$ cm, $\tan\left(\frac{\theta}{2}\right) = \frac{15}{20} = \frac{3}{4}$

$$\therefore \cos\left(\frac{\theta}{2}\right) = \frac{4}{5}$$

$$\therefore \frac{d\theta}{dt} = \frac{1}{10} \left(\frac{4}{5}\right)^2 2 = 0.128$$

$\therefore \theta$ is increasing at 0.128 radians per second

13

Let $QR = x$ cm and the angle at P be θ .

$$\text{Then } \tan \theta = \frac{x}{6}$$

$$\therefore \sec^2 \theta \frac{d\theta}{dt} = \frac{1}{6} \frac{dx}{dt}$$

$$\therefore \frac{d\theta}{dt} = \frac{\cos^2 \theta}{6} \frac{dx}{dt} \quad \text{where } \frac{dx}{dt} = 2 \text{ cm min}^{-1}$$

Particular case: When $x = 8$ cm, $PR = 10$ cm

$$\text{Now } \cos \theta = \frac{6}{10}, \text{ so } \frac{d\theta}{dt} = \left(\frac{6}{10}\right)^2 \times \frac{1}{6} \times 2 = 0.12$$

$\therefore$ the angle at P is increasing at a rate of 0.12 radians per minute.

14 Let x and y be the distances the cyclists A and B have travelled respectively at time t , and let z be the distance between them.

$$\text{So, } z^2 = x^2 + y^2 - 2xy \cos 120^\circ \quad \{\text{cosine rule}\}$$

$$\therefore z^2 = x^2 + y^2 + xy \quad \dots (1)$$

$$\therefore 2z \frac{dz}{dt} = 2x \frac{dx}{dt} + 2y \frac{dy}{dt} + \frac{dx}{dt} y + x \frac{dy}{dt} \quad \dots (2)$$

Particular case:

$$\text{After 2 minutes, } t = 120 \text{ s, } x = 1440 \text{ m, } y = 1920 \text{ m, } \frac{dx}{dt} = 12 \text{ m s}^{-1}, \text{ and } \frac{dy}{dt} = 16 \text{ m s}^{-1}.$$

$$\text{Using (1), } z^2 = 1440^2 + 1920^2 + 1440 \times 1920 = 8\,524\,800$$

$$\therefore 960\sqrt{37} \frac{dz}{dt} = 142\,080$$

$$\therefore \frac{dz}{dt} = \frac{148}{\sqrt{37}} = 4\sqrt{37} \approx 24.33$$

$\therefore$ the distance between the cyclists is increasing at 24.3 m s^{-1} .

Let $AP = l$ cm and let $\widehat{AOP} = \theta$

$$\therefore l^2 = 5^2 + 5^2 - 2 \times 5 \times 5 \cos \theta \quad \{\text{cosine rule}\}$$

$$\therefore l^2 = 50 - 50 \cos \theta$$

$$\therefore 2l \frac{dl}{dt} = 50 \sin \theta \frac{d\theta}{dt}$$

$$\therefore \frac{dl}{dt} = \frac{25 \sin \theta}{l} \frac{d\theta}{dt}$$

Now the point moves at one revolution every 10 seconds.

$$\therefore \frac{d\theta}{dt} = \frac{2\pi}{10} = \frac{\pi}{5} \text{ radians per second}$$

Particular cases:

a If $AP = l = 5$ cm, $\frac{dl}{dt} > 0$,
then $\theta = \frac{\pi}{3}$ $\{\triangle APO \text{ is equilateral}\}$

$$\begin{aligned} \therefore \frac{dl}{dt} &= \frac{25 \sin(\frac{\pi}{3})}{5} \times \frac{\pi}{5} \\ &= \frac{\sqrt{3}}{2} \pi \text{ cm s}^{-1} \end{aligned}$$

b If P is at B, then $l = 10$ cm

and $\theta = \pi$

$$\begin{aligned} \therefore \frac{dl}{dt} &= \frac{25 \sin \pi}{10} \times \frac{\pi}{5} \\ &= 0 \text{ cm s}^{-1} \end{aligned}$$

16

Let $\widehat{AOB} = \phi$ and $\widehat{ABO} = \theta$ Now $\frac{d\phi}{dt} = -100$ revolutions per second
{negative for clockwise rotation}

$$\therefore \frac{d\phi}{dt} = -200\pi \text{ radians per second}$$

$$\text{Also, } \frac{30}{\sin \phi} = \frac{15}{\sin \theta} \quad \{\text{sine rule}\}$$

$$\therefore \sin \phi = 2 \sin \theta$$

$$\therefore \cos \phi \frac{d\phi}{dt} = 2 \cos \theta \frac{d\theta}{dt}$$

$$\therefore \frac{d\theta}{dt} = \frac{1}{2} \frac{\cos \phi}{\cos \theta} \frac{d\phi}{dt}$$

$$\text{where } \frac{d\phi}{dt} = -200\pi \text{ radians s}^{-1}$$

Particular cases:

a When $\widehat{AOX} = 120^\circ$, $\phi = \frac{2\pi}{3}$

$$\therefore \cos \phi = -\frac{1}{2} \text{ and } \sin \phi = \frac{\sqrt{3}}{2}$$

$$\begin{aligned} \therefore \sin \theta &= \frac{1}{2} \sin \phi \\ &= \frac{1}{2} \left(\frac{\sqrt{3}}{2} \right) \\ &= \frac{\sqrt{3}}{4} \\ \therefore \cos \theta &= \frac{\sqrt{13}}{4} \end{aligned}$$

$$\therefore \frac{d\theta}{dt} = \frac{1}{2} \times \frac{-\frac{1}{2}}{\frac{\sqrt{13}}{4}} \times (-200\pi) = \frac{200\pi}{\sqrt{13}}$$

$\therefore \widehat{ABO}$ is increasing at $\frac{200\pi}{\sqrt{13}}$ radians per second.

b When $\widehat{AOX} = 180^\circ$, $\phi = \pi$,

$$\therefore \cos \phi = -1 \text{ and } \sin \phi = 0$$

$$\therefore \sin \theta = 0 \text{ and } \cos \theta = 1$$

$$\begin{aligned} \therefore \frac{d\theta}{dt} &= \frac{1}{2} \times \frac{-1}{1} \times (-200\pi) \\ &= 100\pi \end{aligned}$$

$\therefore \widehat{ABO}$ is increasing at 100π radians per second.

 Denote the radius of the semi-circle $r = \frac{1}{2}$ m.

 Let h be the depth and V be the volume of water in the trough at time t .

- a** The cross-sectional area of water in the trough
 = area of sector – area of triangle
 = $\frac{1}{2}r^2\theta - \frac{1}{2}r^2\sin\theta$
 = $\frac{1}{2}r^2(\theta - \sin\theta)$
 = $\frac{1}{8}(\theta - \sin\theta)$
 $\therefore$ the volume of water,

$$\begin{aligned} V &= \text{area of water} \times \text{length of trough} \\ &= \frac{1}{8}(\theta - \sin\theta) \times 8 \\ &= \theta - \sin\theta \quad \text{as required} \end{aligned}$$

b Now $\frac{dV}{dt} = \frac{d\theta}{dt} - \cos\theta \frac{d\theta}{dt}$
 $\therefore \frac{dV}{dt} = \frac{d\theta}{dt}(1 - \cos\theta)$
 But $\frac{dV}{dt} = 0.1 \text{ m}^3 \text{ min}^{-1}$
 $\therefore \frac{d\theta}{dt} = \frac{0.1}{1 - \cos\theta} \dots (1)$

Also, $\cos\left(\frac{\theta}{2}\right) = \frac{\frac{1}{2} - h}{\frac{1}{2}} = 1 - 2h$

 Differentiating with respect to t ,

$$\begin{aligned} -\sin\left(\frac{\theta}{2}\right) \times \frac{1}{2} \frac{d\theta}{dt} &= -2 \frac{dh}{dt} \\ \therefore \frac{dh}{dt} &= \frac{1}{4} \sin\left(\frac{\theta}{2}\right) \frac{d\theta}{dt} \dots (2) \end{aligned}$$

Particular case:

When $h = 0.25$ m, $\cos\left(\frac{\theta}{2}\right) = \frac{r-h}{r} = \frac{\frac{1}{2} - \frac{1}{4}}{\frac{1}{2}} = \frac{\frac{1}{4}}{\frac{1}{2}} = \frac{1}{2}$
 $\therefore \sin\left(\frac{\theta}{2}\right) = \frac{\sqrt{3}}{2}$ and $\cos\theta = 2\cos^2\left(\frac{\theta}{2}\right) - 1 = 2\left(\frac{1}{2}\right)^2 - 1 = -\frac{1}{2}$

Using (1), $\frac{d\theta}{dt} = \frac{0.1}{1 - (-\frac{1}{2})} = \frac{1}{15}$ $\therefore \theta$ is increasing at $\frac{1}{15}$ radians per minute.

Using (2), $\frac{dh}{dt} = \frac{1}{4} \sin\left(\frac{\theta}{2}\right) \frac{d\theta}{dt}$
 $= \frac{1}{4} \times \frac{\sqrt{3}}{2} \times \frac{1}{15}$
 $= \frac{\sqrt{3}}{120}$ $\therefore h$ is increasing at $\frac{\sqrt{3}}{120}$ metres per minute.

$$\text{So, } \frac{dA}{dx} = 0 \text{ when } x = 6, \text{ and } \frac{dA}{dx} \text{ has sign diagram:}$$

The maximum water is held when $x = 6$ cm

$$\begin{aligned}\therefore a(t) &= -8(t+1)^{-3} \\ &= -\frac{8}{(t+1)^3} \text{ cm s}^{-2}\end{aligned}$$

b $s(1) = 2(1) - \frac{4}{(1+1)} = 0 \text{ cm}$
 $v(1) = 2 + \frac{4}{(1+1)^2} = 3 \text{ cm s}^{-1}$
 $a(1) = -\frac{8}{(1+1)^3} = -1 \text{ cm s}^{-2}$

$\therefore$ the particle is at the origin and is moving to the right with velocity 3 cm s^{-1} and slowing down, its acceleration being 1 cm s^{-2} to the left.

c $v(t) = 2 + \frac{4}{(t+1)^2} = \frac{2(t+1)^2 + 4}{(t+1)^2}$

$\therefore v(t) \neq 0$ for any real t , so the particle never changes direction.

- e** **i** The velocity is never increasing {acceleration is negative for all $t > 0$ }.
ii The speed is never increasing, as $v(t)$ and $a(t)$ have different signs for all $t > 0$.

- 6** When the box is manufactured its base is $(2k - 2x)$ by $(k - 2x)$ and its height is $x \text{ cm}$.

$$\begin{aligned}\therefore V &= x(2k - 2x)(k - 2x) \\ \therefore V &= x(2k^2 - 4kx - 2xk + 4x^2) \\ &= 2k^2x - 6kx^2 + 4x^3 \\ \therefore \frac{dV}{dx} &= 2k^2 - 12kx + 12x^2 \\ &= 2(6x^2 - 6kx + k^2)\end{aligned}$$

So, $\frac{dV}{dx} = 0$ when $x = \frac{6k \pm \sqrt{36k^2 - 4(6)k^2}}{12}$

$$\begin{aligned}&= \frac{6k \pm k\sqrt{12}}{12} \\ &= \frac{k}{2} \pm \frac{k}{\sqrt{12}} \\ &= \frac{k}{2} - \frac{k}{2\sqrt{3}} \quad \{\text{as } x \leq \frac{k}{2}\} \\ &= \frac{k}{2} \left(1 - \frac{1}{\sqrt{3}}\right)\end{aligned}$$

The sign diagram of $\frac{dV}{dx}$ is:

$\therefore$ the maximum capacity occurs when $x = \frac{k}{2} \left(1 - \frac{1}{\sqrt{3}}\right)$.

- 7 a** $s(t) = 30 + \cos(\pi t) \text{ cm}, \quad t \geq 0$

$$\therefore v(t) = s'(t) = -\pi \sin(\pi t)$$

So, $v(0) = 0 \text{ cm s}^{-1}, \quad v(\frac{1}{2}) = -\pi \text{ cm s}^{-1},$
 $v(1) = 0 \text{ cm s}^{-1}, \quad v(\frac{3}{2}) = \pi \text{ cm s}^{-1},$
 $v(2) = 0 \text{ cm s}^{-1}$

Sign diagram of $v(t)$ is:

- b** The cork is falling when $v(t) \leq 0$, which is for $0 \leq t \leq 1, 2 \leq t \leq 3, 4 \leq t \leq 5, \dots$
 $\therefore$ the cork is falling for $2n \leq t \leq 2n + 1, \quad n \in \{0, 1, 2, 3, \dots\}$

- 8 a**

Using the cosine rule: in $\triangle PQR$, $PR^2 = a^2 + b^2 - 2ab \cos \theta$
 in $\triangle PSR$, $PR^2 = c^2 + d^2 - 2cd \cos \phi$

$$\therefore a^2 + b^2 - 2ab \cos \theta = c^2 + d^2 - 2cd \cos \phi$$

b Now a , b , c , and d are constants, so differentiating with respect to ϕ ,

$$\begin{aligned}\therefore 2ab \sin \theta \frac{d\theta}{d\phi} &= 2cd \sin \phi \\ \therefore \frac{d\theta}{d\phi} &= \frac{2cd \sin \phi}{2ab \sin \theta} = \frac{cd \sin \phi}{ab \sin \theta} \quad \text{as required}\end{aligned}$$

c Area of quadrilateral, $A = \text{area of } \triangle PQR + \text{area of } \triangle PSR$

$$\begin{aligned}&= \frac{1}{2}ab \sin \theta + \frac{1}{2}cd \sin \phi \\ \therefore \frac{dA}{d\phi} &= \frac{1}{2}ab \cos \theta \frac{d\theta}{d\phi} + \frac{1}{2}cd \cos \phi \\ &= \frac{1}{2}ab \cos \theta \left(\frac{cd \sin \phi}{ab \sin \theta} \right) + \frac{1}{2}cd \cos \phi \quad \{\text{using a}\} \\ &= \frac{1}{2}cd \left[\frac{\cos \theta \sin \phi}{\sin \theta} + \cos \phi \right] \\ &= \frac{cd}{2 \sin \theta} (\sin \phi \cos \theta + \cos \phi \sin \theta) \\ &= \frac{cd}{2 \sin \theta} \sin(\phi + \theta) \\ \therefore \frac{dA}{d\phi} &= 0 \quad \text{when } \sin(\phi + \theta) = 0, \quad \text{which is when } \phi + \theta = \pi\end{aligned}$$

$\therefore$ the area of PQRS is a maximum when the opposite angles are supplementary, which occurs when PQRS is a cyclic quadrilateral.

9 Let the coordinates of A be $(x, 0)$

$\therefore$ the coordinates of P are (x, ae^{-x})

OAPB has perimeter $P = 2(x + ae^{-x})$
 $= 2x + 2ae^{-x}$

$$\begin{aligned}\therefore \frac{dP}{dx} &= 2 - 2ae^{-x} \\ &= 2 \left(1 - \frac{a}{e^x} \right)\end{aligned}$$

Now $\frac{dP}{dx} = 0$ when $1 = \frac{a}{e^x}$

$$\therefore e^x = a$$

$$\therefore x = \ln a$$

$\therefore$ there is a local minimum when $x = \ln a$

When $x = \ln a$, $y = ae^{-(\ln a)} = \frac{a}{e^{\ln a}} = 1$

$\therefore$ rectangle OAPB has minimum perimeter when P is at $(\ln a, 1)$.

$$v(8) = 3 - \frac{1}{2\sqrt{8+1}} \approx 2.83 \text{ cm s}^{-1}$$

$$a(8) = \frac{1}{4(8+1)^{\frac{3}{2}}} \approx 0.009\,26 \text{ cm s}^{-2}$$

The particle is 21 cm to the right of the origin, is travelling to the right at 2.83 cm s^{-1} , and accelerating at $0.009\,26 \text{ cm s}^{-2}$.

d Since $v(t)$ is > 0 for all $t \geq 0$, the particle never changes direction.

Let the height of the cylinder be h cm.

∴ $V(x) = \text{area of base} \times \text{height}$

$= \pi x^2 \times \sqrt{100 - 4x^2}$

So, $V(x) = \pi x^2 \sqrt{100 - 4x^2} \text{ cm}^3$

b Now $V^2 = \pi^2 x^4 (100 - 4x^2)$

∴ $\frac{d(V^2)}{dx} = 0$ when $x = \sqrt{\frac{50}{3}}$ {as $x > 0$ }

∴ maximum V occurs when $x = \sqrt{\frac{50}{3}} \approx 4.08$

9 Let t be the number of seconds after A passes through X. In this time, A travels $5t$ m.

B passes through X when $t = 3$.

∴ for $t > 3$, B is $4(t - 3)$ m from X.

Using the cosine rule,

$D^2 = 25t^2 + 16(t - 3)^2 - 2 \times 5t \times 4(t - 3) \times \cos 60^\circ$
 $= 25t^2 + 16(t - 3)^2 - 20t(t - 3)$

∴ $2D \frac{dD}{dt} = 50t + 32(t - 3) - 20(t - 3) - 20t$

When $5t = 20$, $t = 4$ and $D^2 = 25 \times 16 + 16 - 20 \times 4 = 336$

∴ $2\sqrt{336} \frac{dD}{dt} = 200 + 32 - 20 - 80 = 132$

$$\therefore \frac{dT}{d\theta} = \frac{r(a+r)\sin\theta}{v \times \frac{r\sin\theta}{\sin\alpha}} - \frac{rv}{vw}$$

$$= \frac{a+r}{v} \sin\alpha - \frac{rv}{vw}$$

$$= \frac{a+r}{v} \left(\sin\alpha - \frac{rv}{(a+r)w} \right)$$

c Now $a+r \neq 0$ so $\frac{dT}{d\theta} = 0$ when $\sin\alpha - \frac{rv}{(a+r)w} = 0$

$$\therefore \sin\alpha = \frac{rv}{(a+r)w}$$

Sign diagram for $\frac{dT}{d\theta}$ is:

$\therefore T$ is minimised when $\sin\alpha = \frac{rv}{(a+r)w}$

EXERCISE 21A.1

1 a i

The rectangles are $\frac{1}{5} = 0.2$ units wide.

$$\begin{aligned} A_U &= 0.2 \times f(0.2) + 0.2 \times f(0.4) + 0.2 \times f(0.6) \\ &\quad + 0.2 \times f(0.8) + 0.2 \times f(1) \\ &= 0.2 \times 0.2 + 0.2 \times 0.4 + 0.2 \times 0.6 \\ &\quad + 0.2 \times 0.8 + 0.2 \times 1 \\ &= 0.6 \text{ units}^2 \end{aligned}$$

ii

$$\begin{aligned} A_L &= 0.2 \times f(0) + 0.2 \times f(0.2) + 0.2 \times f(0.4) \\ &\quad + 0.2 \times f(0.6) + 0.2 \times f(0.8) \\ &= 0.2 \times 0 + 0.2 \times 0.2 + 0.2 \times 0.4 \\ &\quad + 0.2 \times 0.6 + 0.2 \times 0.8 \\ &= 0.4 \text{ units}^2 \end{aligned}$$

b The area between $y = x$ and the x -axis from $x = 0$ to $x = 1$ is a triangle.

$$\begin{aligned} \therefore \text{area} &= \frac{1}{2} \times \text{base} \times \text{height} \\ &= \frac{1}{2} \times 1 \times 1 \\ &= \frac{1}{2} \text{ unit}^2 \end{aligned}$$

$\therefore A_L < \text{area} < A_U$, and both A_L and A_U are within 0.1 unit^2 , or 20%, of the actual area.

2 The rectangles are $\frac{2}{6} = \frac{1}{3}$ units wide.

b

$$\begin{aligned} A_L &= \frac{1}{3} f\left(\frac{7}{3}\right) + \frac{1}{3} f\left(\frac{8}{3}\right) + \frac{1}{3} f(3) + \frac{1}{3} f\left(\frac{10}{3}\right) \\ &\quad + \frac{1}{3} f\left(\frac{11}{3}\right) + \frac{1}{3} f(4) \\ &= \frac{1}{3} \times \frac{3}{7} + \frac{1}{3} \times \frac{3}{8} + \frac{1}{3} \times \frac{1}{3} + \frac{1}{3} \times \frac{3}{10} \\ &\quad + \frac{1}{3} \times \frac{3}{11} + \frac{1}{3} \times \frac{1}{4} \\ &\approx 0.653 \text{ units}^2 \end{aligned}$$

Check: The area is a quarter circle with radius 3 units.

$$\begin{aligned}\therefore \text{area} &= \frac{1}{4}\pi r^2 \\ &= \frac{1}{4} \times \pi \times 3^2 = \frac{9}{4}\pi \approx 7.07 \text{ units}^2 \quad \checkmark\end{aligned}$$

5 a

If $\frac{d}{dx} F(x) = f(x)$ then $\frac{d}{dx} (-F(x)) = -f(x)$

$$\begin{aligned}\therefore \int_a^b (-f(x)) dx &= -F(b) - (-F(a)) \\ &= -(F(b) - F(a)) \\ &= -\int_a^b f(x) dx\end{aligned}$$

c i $\int_0^1 (-x^2) dx = -\int_0^1 x^2 dx$

Now $f(x) = x^2$ has antiderivative

ii $\int_0^1 (x^2 - x) dx = -\int_0^1 (x - x^2) dx$

$$\{x^2 - x \leq 0 \text{ for all } x \in [0, 1]\}$$

Now $f(x) = x - x^2$ has antiderivative

$$F(x) = \frac{1}{2}x^2 - \frac{1}{3}x^3$$

$$\begin{aligned}\therefore \int_0^1 (x^2 - x) dx &= -(F(1) - F(0)) \\ &= -\left(\frac{1}{2} - \frac{1}{3} - (0 - 0)\right) \\ &= -\frac{1}{6}\end{aligned}$$

The shaded region has area $\frac{1}{6} \text{ units}^2$.

$$\text{iii} \quad \int_{-2}^0 3x \, dx = - \int_{-2}^0 -3x \, dx$$

Now $f(x) = -3x$ has antiderivative $F(x) = -\frac{3}{2}x^2$

$$\therefore \int_{-2}^0 3x \, dx = - (F(0) - F(-2))$$

$$= - (0 - (-6))$$

$$= -6$$

The shaded region has area 6 units².

$$\text{d} \quad \int_0^2 (-\sqrt{4-x^2}) \, dx = - \int_0^2 \sqrt{4-x^2} \, dx$$

Now $f(x) = \sqrt{4-x^2}$ is the top half of a circle with radius 2 units and centre (0, 0).

$$\therefore \int_0^2 (-\sqrt{4-x^2}) \, dx = - \int_0^2 \sqrt{4-x^2} \, dx$$

10 Given: $f'(x) = p \sin\left(\frac{1}{2}x\right)$, $f(0) = 1$ and $f(2\pi) = 0$

$$\therefore f(x) = -2p \cos\left(\frac{1}{2}x\right) + c$$

11 $g''(x) = -\sin 2x$

Integrating both sides with respect to x , we get $g'(x) = \frac{1}{2} \cos 2x + c$, c some constant.

$$\begin{aligned} \text{So, } g'(\pi) &= \frac{1}{2} \cos(2\pi) + c & \text{and} & & g'(-\pi) &= \frac{1}{2} \cos(-2\pi) + c \\ &= \frac{1}{2} + c & & & &= \frac{1}{2} + c \\ & & & & &= g'(\pi) \end{aligned}$$

$\therefore$ the gradients of the tangents to $y = g(x)$ at $x = \pi$ and $x = -\pi$ are equal.

 But $f(0) = 3$ so $-e^0 + c = 3$
 $\therefore c = 4$
 $\therefore f(x) = -e^{-2x} + 4$

 But $f(-1) = 3$ so $1 + 2 \ln|2| + c = 3$
 $\therefore c = 2 - 2 \ln 2$
 $\therefore f(x) = x^2 + 2 \ln|1-x| + 2 - 2 \ln 2$

c $f'(x) = \sqrt{x} + \frac{1}{2}e^{-4x}$
 $= x^{\frac{1}{2}} + \frac{1}{2}e^{-4x}$
 $\therefore f(x) = \frac{x^{\frac{3}{2}}}{\frac{3}{2}} + \frac{1}{2}\left(\frac{1}{-4}\right)e^{-4x} + c$
 $= \frac{2}{3}x^{\frac{3}{2}} - \frac{1}{8}e^{-4x} + c$

But $f(1) = 0$
 $\therefore \frac{2}{3} - \frac{1}{8}e^{-4} + c = 0$
 $\therefore c = \frac{1}{8}e^{-4} - \frac{2}{3}$
 $\therefore f(x) = \frac{2}{3}x^{\frac{3}{2}} - \frac{1}{8}e^{-4x} + \frac{1}{8}e^{-4} - \frac{2}{3}$

13 $(\sin x + \cos x)^2 = \sin^2 x + 2 \sin x \cos x + \cos^2 x$
 $= 1 + \sin 2x$
 $\therefore \int (\sin x + \cos x)^2 dx = \int (1 + \sin 2x) dx$
 $= x - \frac{1}{2} \cos(2x) + c$

14 $(\cos x + 1)^2 = \cos^2 x + 2 \cos x + 1$
 $= \left(\frac{1}{2} + \frac{1}{2} \cos 2x\right) + 2 \cos x + 1$
 $= \frac{1}{2} \cos 2x + 2 \cos x + \frac{3}{2}$
 $\therefore \int (\cos x + 1)^2 dx = \int \left(\frac{1}{2} \cos 2x + 2 \cos x + \frac{3}{2}\right) dx$
 $= \frac{1}{4} \sin 2x + 2 \sin x + \frac{3}{2}x + c$

15 $\frac{3}{x+2} - \frac{1}{x-2} = \frac{3(x-2) - 1(x+2)}{(x+2)(x-2)}$
 $= \frac{3x - 6 - x - 2}{x^2 - 4}$
 $= \frac{2x - 8}{x^2 - 4}$

$\therefore \int \frac{2x-8}{x^2-4} dx = \int \left(\frac{3}{x+2} - \frac{1}{x-2}\right) dx$
 $= 3 \ln|x+2| - \ln|x-2| + c$

16 $\frac{1}{2x-1} - \frac{1}{2x+1} = \frac{1(2x+1) - 1(2x-1)}{(2x-1)(2x+1)}$
 $= \frac{2x+1-2x+1}{(2x-1)(2x+1)}$
 $= \frac{2}{4x^2-1}$

$\therefore \int \frac{2}{4x^2-1} dx$
 $= \int \left(\frac{1}{2x-1} - \frac{1}{2x+1}\right) dx$
 $= \frac{1}{2} \ln|2x-1| - \frac{1}{2} \ln|2x+1| + c$

Now $\sin \theta = \frac{x}{2}$, $\cos \theta = \frac{\sqrt{4-x^2}}{2}$

$$\therefore \sin 2\theta = 2 \left(\frac{x}{2} \right) \frac{\sqrt{4-x^2}}{2} = \frac{x\sqrt{4-x^2}}{2}$$

$$\therefore \sin 4\theta = 2 \left(\frac{x\sqrt{4-x^2}}{2} \right) \left(\frac{4-2x^2}{4} \right)$$

$$= \frac{x\sqrt{4-x^2}(2-x^2)}{2}$$

EXERCISE 21H

- 1 a** We integrate by parts with

$$\begin{aligned} u &= x & v' &= e^x \\ u' &= 1 & v &= e^x \end{aligned}$$

$$\begin{aligned} \therefore \int x e^x dx &= x e^x - \int 1 e^x dx \\ &= x e^x - e^x + c \end{aligned}$$

- c** We integrate by parts with

$$\begin{aligned} u &= \ln x & v' &= x^2 \\ u' &= \frac{1}{x} & v &= \frac{x^3}{3} \end{aligned}$$

$$\begin{aligned} \therefore \int x^2 \ln x dx &= \ln x \left(\frac{x^3}{3} \right) - \int \frac{1}{x} \frac{x^3}{3} dx \\ &= \frac{x^3 \ln x}{3} - \frac{1}{3} \int x^2 dx \\ &= \frac{x^3 \ln x}{3} - \frac{1}{3} \frac{x^3}{3} + c \\ &= \frac{1}{3} x^3 \ln x - \frac{1}{9} x^3 + c \end{aligned}$$

- e** We integrate by parts with

$$\begin{aligned} u &= x & v' &= \cos 2x \\ u' &= 1 & v &= \frac{1}{2} \sin 2x \end{aligned}$$

$$\begin{aligned} \therefore \int x \cos 2x dx &= x \left(\frac{1}{2} \sin 2x \right) - \int \frac{1}{2} \sin 2x dx \\ &= \frac{1}{2} x \sin 2x - \frac{1}{2} \left(-\frac{1}{2} \right) \cos 2x + c \\ &= \frac{1}{2} x \sin 2x + \frac{1}{4} \cos 2x + c \end{aligned}$$

- 2 a** $\int \ln x dx = \int 1 \times \ln x dx$

So, we integrate by parts with

$$\begin{aligned} u &= \ln x & v' &= 1 \\ u' &= \frac{1}{x} & v &= x \end{aligned}$$

$$\begin{aligned} \therefore \int \ln x dx &= x \ln x - \int \left(\frac{1}{x} \right) x dx \\ &= x \ln x - \int 1 dx \\ &= x \ln x - x + c \end{aligned}$$

- 3** $\int \arctan x dx = \int 1 \arctan x dx$

So, we integrate by parts with

$$\begin{aligned} u &= \arctan x & v' &= 1 \\ u' &= \frac{1}{x^2 + 1} & v &= x \end{aligned}$$

- b** We integrate by parts with

$$\begin{aligned} u &= x & v' &= \sin x \\ u' &= 1 & v &= -\cos x \end{aligned}$$

$$\begin{aligned} \therefore \int x \sin x dx &= x(-\cos x) - \int 1(-\cos x) dx \\ &= -x \cos x + \int \cos x dx \\ &= -x \cos x + \sin x + c \end{aligned}$$

- d** We integrate by parts with

$$\begin{aligned} u &= x & v' &= \sin 3x \\ u' &= 1 & v &= -\frac{1}{3} \cos 3x \end{aligned}$$

- f** We integrate by parts with

$$\begin{aligned} u &= x & v' &= \sec^2 x \\ u' &= 1 & v &= \tan x \end{aligned}$$

$$\begin{aligned} \therefore \int x \sec^2 x dx &= x \tan x - \int \tan x dx \\ &= x \tan x + \int \frac{-\sin x}{\cos x} dx \\ &= x \tan x + \ln |\cos x| + c \end{aligned}$$

- b** $\int (\ln x)^2 dx = \int (\ln x) (\ln x) dx$

So, we integrate by parts with

$$\begin{aligned} u &= \ln x & v' &= \ln x \\ u' &= \frac{1}{x} & v &= x \ln x - x \quad \{\text{using 9}\} \end{aligned}$$

$$\begin{aligned} \therefore \int (\ln x)^2 dx &= \ln x (x \ln x - x) - \int \frac{1}{x} (x \ln x - x) dx \\ &= x(\ln x)^2 - x \ln x - \int (\ln x - 1) dx \\ &= x(\ln x)^2 - x \ln x - [x \ln x - x] + x + c \\ &= x(\ln x)^2 - 2x \ln x + 2x + c \end{aligned}$$

$$\therefore \int \arctan x dx$$

$$= x \arctan x - \int \frac{x}{x^2 + 1} dx$$

We again integrate by parts with $u = e^x \quad v' = \sin x$
 $u' = e^x \quad v = -\cos x$

$$\begin{aligned}\therefore \int e^x \cos x dx &= e^x \sin x - \left[-e^x \cos x - \int e^x(-\cos x) dx \right] + c \\ &= e^x \sin x + e^x \cos x - \int e^x \cos x dx + c\end{aligned}$$

$$\therefore 2 \int e^{-x} \sin x dx = -e^{-x} (\sin x + \cos x) + c$$

$$\therefore \int e^{-x} \sin x dx = -\frac{1}{2} e^{-x} (\sin x + \cos x) + c$$

- d** We integrate by parts with $u = x^2 \quad v' = \sin x$
 $u' = 2x \quad v = -\cos x$

$$\begin{aligned}\therefore \int x^2 \sin x dx &= -x^2 \cos x - \int -2x \cos x dx \\ &= -x^2 \cos x + \int 2x \cos x dx\end{aligned}$$

- 5 a** We integrate by parts with $a = u^2 \quad b' = e^u$
 $a' = 2u \quad b = e^u$

$$\begin{aligned}\therefore \int u^2 e^u du &= u^2 e^u - \int 2u e^u du \\ &= u^2 e^u - 2 \int u e^u du\end{aligned}$$

We integrate by parts again, this time with $a = u$ $b' = e^u$
 $a' = 1$ $b = e^u$

b Let $u = \ln x$, $\frac{du}{dx} = \frac{1}{x} = \frac{1}{e^u}$ $\therefore \int (\ln x)^2 dx = \int u^2 e^u du$
 $= u^2 e^u - 2 u e^u + 2 e^u + c$ {using **a**}
 $= (\ln x)^2 e^{\ln x} - 2 \ln x e^{\ln x} + 2 e^{\ln x} + c$

6 a We integrate by parts with $a = u$ $b' = \sin u$
 $a' = 1$ $b = -\cos u$

$$\begin{aligned}\therefore \int u \sin u du &= -u \cos u - \int -\cos u du \\ &= -u \cos u + \sin u + c\end{aligned}$$

$$\mathbf{15} \quad \text{Let } u = \cos x, \quad \frac{du}{dx} = -\sin x$$

d The curve cuts the x -axis when $y = 0$.

$$\therefore 3x^2 - 8x + 4 = 0$$

$$\therefore (3x - 2)(x - 2) = 0$$

$$\therefore x = 2 \text{ or } \frac{2}{3}$$

$\therefore$ the x -intercepts are 2 and $\frac{2}{3}$.

$$\begin{aligned} \text{Area} &= \int_{\frac{2}{3}}^2 [0 - (3x^2 - 8x + 4)] dx \\ &= \int_{\frac{2}{3}}^2 (-3x^2 + 8x - 4) dx \\ &= \left[-x^3 + 4x^2 - 4x \right]_{\frac{2}{3}}^2 \\ &= (-8 + 16 - 8) - \left(-\frac{8}{27} + \frac{16}{9} - \frac{8}{3} \right) \\ &= 1\frac{5}{27} \text{ units}^2 \end{aligned}$$

f The curve cuts the x -axis when $y = 0$.

$$\therefore x^3 - 4x = 0$$

$$\therefore x(x^2 - 4) = 0$$

2 $y = x^2 - 2x$ meets $y = 3$ when $x^2 - 2x = 3$

$$\therefore x^2 - 2x - 3 = 0$$

3 a**b** The graphs meet where $x - 3 = x^2 - 3x$

$$\therefore x^2 - 3x - x + 3 = 0$$

$$\therefore x^2 - 4x + 3 = 0$$

$$\therefore (x - 1)(x - 3) = 0$$

$$\therefore x = 1 \text{ or } 3$$

4 $y = \sqrt{x}$ meets $y = x^2$ where $\sqrt{x} = x^2$

$$\therefore x = x^4$$

$$\therefore x^4 - x = 0$$

$$\therefore x(x^3 - 1) = 0$$

$$\therefore x(x - 1)(x^2 + x + 1) = 0$$

$$\therefore x = 0 \text{ or } 1$$

The factor $(x^2 + x + 1)$ has no real root since $\Delta = -3$ which is < 0 .

$$= \frac{2}{3} - \frac{1}{3}$$

$$= \frac{1}{3} \text{ unit}^2$$

5 a $y = e^x - 1$ has no vertical asymptotes.

As $x \rightarrow \infty$, $e^x - 1 \rightarrow \infty$

As $x \rightarrow -\infty$, $e^x \rightarrow 0$

so $e^x - 1 \rightarrow -1^+$

$\therefore y = -1$ is a horizontal asymptote.

$y = 0$ when $e^x - 1 = 0$

$$\therefore e^x = 1$$

$$\therefore x = 0$$

$\therefore x$ -intercept is $(0, 0)$.

This is also the y -intercept.

 $y = 2 - 2e^{-x}$ has no vertical asymptotes.

As $x \rightarrow \infty$, $e^{-x} \rightarrow 0$

so $2 - 2e^{-x} \rightarrow 2^-$

$\therefore y = 2$ is a horizontal asymptote.

$y = 0$ when $2 - 2e^{-x} = 0$

$$\therefore e^{-x} = 1$$

$$\therefore x = 0$$

$\therefore x$ -intercept is $(0, 0)$.

This is also the y -intercept.

b $y = e^x - 1$ meets $y = 2 - 2e^{-x}$
 where $e^x - 1 = 2 - 2e^{-x}$
 $\therefore e^{2x} - e^x = 2e^x - 2 \quad \{\times e^x\}$
 $\therefore e^{2x} - 3e^x + 2 = 0$
 $\therefore (e^x - 1)(e^x - 2) = 0$

 $= (3 \ln 2 - 2 + 1) - (0 - 1 + 2)$
 $= 3 \ln 2 - 2$
 $\approx 0.0794 \text{ units}^2$

6 $y = 2e^x$ meets $y = e^{2x}$ where
 $2e^x = e^{2x}$
 $\therefore e^{2x} - 2e^x = 0$
 $\therefore e^x(e^x - 2) = 0$
 $\therefore e^x = 2 \quad \{e^x > 0 \text{ for all } x\}$
 $\therefore x = \ln 2$
 Area $= \int_0^{\ln 2} (2e^x - e^{2x}) dx$

7 a $y = 2x$ meets $y = 4x^2$ where
 $2x = 4x^2$
 $\therefore 4x^2 - 2x = 0$
 $\therefore 2x(2x - 1) = 0$
 $\therefore x = 0 \text{ or } \frac{1}{2}$

Area

 $= [x^2 - \frac{4}{3}x^3]_0^{\frac{1}{2}}$
 $= (\frac{1}{4} - \frac{4}{3}(\frac{1}{8})) - (0 - 0)$
 $= \frac{1}{12} \text{ unit}^2$

b $y = 2x$ meets $y^2 = 4x$ where
 $(2x)^2 = 4x$
 $\therefore 4x^2 = 4x$
 $\therefore 4x^2 - 4x = 0$
 $\therefore 4x(x - 1) = 0$
 $\therefore x = 0 \text{ or } 1$
 The upper part of $y^2 = 4x$

9

The curves $y = \cos x$ and $y = \sin x$ meet when $x = \frac{\pi}{4}$.

$$\begin{aligned}\therefore A &= \int_0^{\frac{\pi}{4}} (\cos x - \sin x) dx \\ &= [\sin x + \cos x]_0^{\frac{\pi}{4}} \\ &= \left(\sin \frac{\pi}{4} + \cos \frac{\pi}{4}\right) - (\sin 0 + \cos 0) \\ &= \left(\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}\right) - (0 + 1) \\ &= (\sqrt{2} - 1) \text{ units}^2\end{aligned}$$

- 10 a** Point A has y -coordinate 1 and lies on the graph of $y = \tan x$ on the interval $[0, \frac{\pi}{2}[$.

At this point, $\tan x = 1 \quad \therefore x = \frac{\pi}{4} \quad \therefore A$ is at $(\frac{\pi}{4}, 1)$.

- b** Consider $\tan x = \frac{\sin x}{\cos x}$

$$\text{Let } u = \cos x, \quad \frac{du}{dx} = -\sin x$$

$$\text{When } x = 0, \quad u = \cos 0 = 1$$

$$\text{When } x = \frac{\pi}{4}, \quad u = \cos \frac{\pi}{4} = \frac{1}{\sqrt{2}}$$

- 11 a** Now $x^2 + y^2 = 9 \quad \therefore y^2 = 9 - x^2$
 $\therefore y = \pm \sqrt{9 - x^2}$

In the upper half of the circle all y -values are ≥ 0

$\therefore y = +\sqrt{9 - x^2}$ is the required equation.

- b** The shaded area is A where $A = \int_0^3 \sqrt{9 - x^2} dx$

This is a quarter of the area of a circle with radius 3 units.

$$\therefore A = \frac{1}{4}(\pi \times 3^2) = \frac{9\pi}{4} \approx 7.07 \text{ units}^2$$

- 12 a** $f(x) = x^3 - 9x$
 $= x(x^2 - 9)$
 $= x(x + 3)(x - 3)$
 $\therefore y = f(x)$ cuts the x -axis at $0, \pm 3$

$$\text{Area} = \int_{-3}^0 (x^3 - 9x) dx + \int_0^3 [0 - (x^3 - 9x)] dx$$

$$= \left[\frac{x^4}{4} - \frac{9x^2}{2} \right]_{-3}^0 + \left[-\frac{x^4}{4} + \frac{9x^2}{2} \right]_0^3$$

$$\therefore c = 100$$

$$\therefore v(t) = 100 - 80e^{-\frac{t}{20}} \text{ m s}^{-1}$$

$$\mathbf{a} \quad \text{As } t \rightarrow \infty, e^{-\frac{t}{20}} \rightarrow 0^+ \quad \therefore v(t) \rightarrow 100^- \text{ m s}^{-1}$$

$\therefore$ the object approaches a limiting velocity of 100 m s^{-1} .

$$\begin{aligned}
 \mathbf{b} \quad \text{The total distance travelled} &= \int_0^{10} (100 - 80e^{-\frac{t}{20}}) dt \quad \{v(t) > 0 \text{ for } 0 \leq t \leq 10\} \\
 &= \left[100t + 1600e^{-\frac{t}{20}} \right]_0^{10} \\
 &= \left(1000 + 1600e^{-\frac{1}{2}} \right) - (0 + 1600) \\
 &\approx 370.4 \text{ m}
 \end{aligned}$$

EXERCISE 22D

- 1** The marginal cost is $C'(x)$ and $C'(x) = 3.15 + 0.004x$ € per gadget

$$\begin{aligned}
 \therefore C(x) &= \int (3.15 + 0.004x) dx \\
 &= 3.15x + 0.002x^2 + c
 \end{aligned}$$

$$\text{But } C(0) = 450 \text{ so } c = 450$$

$$\therefore C(x) = 3.15x + 0.002x^2 + 450 \text{ euros}$$

$$\begin{aligned}
 \therefore C(800) &= 3.15(800) + 0.002(800)^2 + 450 \\
 &= \text{€}4250
 \end{aligned}$$

So, the total cost is €4250.

- 2 a** The marginal profit is $P'(x)$ and $P'(x) = 15 - 0.03x$ dollars per plate

$$\begin{aligned}
 \therefore P(x) &= \int (15 - 0.03x) dx \\
 &= 15x - 0.015x^2 + c
 \end{aligned}$$

$$\text{But } P(0) = -650 \text{ so } c = -650$$

$$\therefore P(x) = 15x - 0.015x^2 - 650 \text{ dollars}$$

- b** The maximum profit occurs when $P'(x) = 0$, which is when $15 - 0.03x = 0$

$$\therefore 0.03x = 15$$

$$\therefore x = \frac{15}{0.03}$$

$$\therefore x = 500$$

Now $P''(x) = -0.03 < 0$ $\therefore$ the profit is at a maximum when $x = 500$ plates.

$$\begin{aligned}
 \text{The maximum profit} &= P(500) = 15(500) - 0.015(500)^2 - 650 \\
 &= \$3100
 \end{aligned}$$

- c** In order for a profit to be made, $P(x)$ must be greater than 0

$$\therefore 15x - 0.015x^2 - 650 > 0$$

Using technology, the x -intercepts of $P(x)$ are $x_1 = 45.39$ and $x_2 = 954.6$

Since we cannot produce part plates, a profit is made for $46 \leq x \leq 954$.

$$3 \quad E'(t) = 350(80 + 0.15t)^{0.8} - 120(80 + 0.15t) \text{ calories per day}$$

$$\begin{aligned} \text{Total energy needs over the first week} &= \int_0^7 E'(t) dt \\ &= \int_0^7 [350(80 + 0.15t)^{0.8} - 120(80 + 0.15t)] dt \\ &= \left[\frac{1}{0.15} \times \frac{350(80 + 0.15t)^{1.8}}{1.8} - 9600t - 9t^2 \right]_0^7 \\ &\approx 14\,400 \text{ calories} \end{aligned}$$

$$4 \quad \frac{dT}{dx} = \frac{-20}{x^{0.63}} = -20x^{-0.63} \quad \therefore T = \int -20x^{-0.63} dx \\ = \frac{-20x^{0.37}}{0.37} + c$$

Now when $x = 3$, $T = 100$

$$\begin{aligned} \therefore \frac{-20(3^{0.37})}{0.37} + c &= 100 \\ \therefore c &= 100 + \frac{20(3^{0.37})}{0.37} \approx 181.1639 \\ \therefore T &\approx \frac{-20x^{0.37}}{0.37} + 181.1639 \end{aligned}$$

So, when $x = 6$, $T \approx -104.8925 + 181.1639 \approx 76.27$

$\therefore$ the outer surface temperature is about 76.3°C .

$$5 \quad \mathbf{a} \quad \text{When } x = 0, \text{ deflection} = 0 \quad \therefore y = 0.$$

And when $x = 0$, the tangent is horizontal $\therefore \frac{dy}{dx} = 0$.

$$\begin{aligned} \mathbf{b} \quad \frac{d^2y}{dx^2} &= -\frac{1}{10}(1-x)^2 \\ \therefore \frac{dy}{dx} &= \int -\frac{1}{10}(1-x)^2 dx \\ &= -\frac{1}{10} \left(\frac{1}{-1} \right) \times \frac{(1-x)^3}{3} + c \\ &= \frac{1}{30}(1-x)^3 + c \end{aligned} \quad \begin{aligned} \therefore y &= \int \left[\frac{1}{30}(1-x)^3 - \frac{1}{30} \right] dx \\ &= \frac{1}{30} \left(\frac{1}{-1} \right) \frac{(1-x)^4}{4} - \frac{1}{30}x + d \\ &= -\frac{(1-x)^4}{120} - \frac{x}{30} + d \end{aligned}$$

From **a**, when $x = 0$, $\frac{dy}{dx} = 0$

$$\begin{aligned} \therefore \frac{1}{30}(1-0)^3 + c &= 0 \\ \therefore c &= -\frac{1}{30} \end{aligned}$$

$$\therefore \frac{dy}{dx} = \frac{1}{30}(1-x)^3 - \frac{1}{30}$$

Also from **a**, when $x = 0$, $y = 0$

$$\begin{aligned} \therefore -\frac{1}{120} - 0 + d &= 0 \\ \therefore d &= \frac{1}{120} \end{aligned}$$

$$\therefore y = \frac{1}{120} - \frac{(1-x)^4}{120} - \frac{x}{30}$$

c Maximum deflection occurs at the right hand end where $x \approx 1$

and at $x \approx 1$, $y \approx \frac{1}{120} - 0 - \frac{1}{30} \approx -0.025 \text{ m}$

$\therefore$ the maximum deflection is about 2.5 cm.

$$6 \quad \mathbf{a} \quad \frac{d^2y}{dx^2} = 0.01 \left(2x - \frac{x^2}{2} \right) = 0.02x - 0.005x^2$$

$$\therefore \frac{dy}{dx} = \int (0.02x - 0.005x^2) dx = 0.01x^2 - \frac{0.005}{3}x^3 + c$$

The sag, $y = \int (0.01x^2 - \frac{0.005}{3}x^3 + c) dx$

$$\therefore y = \frac{0.01}{3}x^3 - \frac{0.005}{12}x^4 + cx + d$$

Now when $x = 0$, $y = 0$ $\therefore 0 - 0 + 0 + d = 0$

$$\therefore d = 0$$

$$\therefore y = \frac{0.01}{3}x^3 - \frac{0.005}{12}x^4 + cx$$

Also, when $x = 4$, $y = 0$ $\therefore \frac{0.01}{3}(4^3) - \frac{0.005}{12}(4^4) + 4c = 0$

$$\therefore 4c = \frac{0.005}{12}(4^4) - \frac{0.01}{3}(4^3)$$

$$\therefore c = \frac{0.005}{12}(4^3) - \frac{0.01}{3}(4^2)$$

$$\therefore c = -\frac{0.08}{3}$$

$$\therefore y = \left(\frac{0.01}{3}x^3 - \frac{0.005}{12}x^4 - \frac{0.08}{3}x\right) \text{ m}$$

b The maximum sag occurs when $\frac{dy}{dx} = 0$ $\therefore 0.01x^2 - \frac{0.005}{3}x^3 - \frac{0.08}{3} = 0$
 $\therefore 6x^2 - x^3 - 16 = 0$

Using technology, the three solutions are $x = -1.464$, 2 , and 5.464

But the maximum lies between 0 and 4 , so it must occur when $x = 2$.

When $x = 2$, $y = \frac{0.01}{3}(2^3) - \frac{0.005}{12}(2^4) - \frac{0.08}{3}(2)$

$$\approx -0.03333 \text{ m}$$

$$\approx -3.333 \text{ cm} \quad \therefore \text{the maximum sag is } \approx 3.33 \text{ cm}$$

c At the point 1 m from P , $x = 3 \text{ m}$, so $y = \frac{0.01}{3}(3^3) - \frac{0.005}{12}(3^4) - \frac{0.08}{3}(3)$
 $= -0.02375 \text{ m}$
 $= -2.375 \text{ cm} \quad \therefore \text{the sag is } 2.375 \text{ cm}$

d At the point 1 m from P , $x = 3 \text{ m}$, so $\frac{dy}{dx} = 0.01(3^2) - \frac{0.005}{3}(3^3) - \frac{0.08}{3} \approx 0.0183$
 $\therefore$ the angle θ that the plank makes with the horizontal is such that $\tan \theta \approx 0.0183$
 $\therefore \theta \approx \tan^{-1}(0.0183) \approx 1.05^\circ$

7 The cost per unit volume, $\frac{dC}{dV} = \frac{1}{2}x^2 + 4$ dollars per m^3 (at depth x).

Since the volume of a well $x \text{ m}$ deep is $V = \pi r^2 x$, $\frac{dV}{dx} = \pi r^2$

Now $\frac{dC}{dx} = \frac{dC}{dV} \frac{dV}{dx}$ {chain rule}

$$\therefore \frac{dC}{dx} = \left(\frac{1}{2}x^2 + 4\right) \pi r^2$$

$$\begin{aligned} \therefore C &= \int \frac{dC}{dx} dx \\ &= \int [\pi r^2 (\frac{1}{2}x^2 + 4)] dx \\ &= \pi r^2 \left(\frac{x^3}{6} + 4x\right) + c \end{aligned}$$

So, the cost of digging a well h metres deep

$$= \pi r^2 \left(\frac{h^3}{6} + 4h\right) + c$$

Now if the initial cost $= C_0$ when $h = 0$,

$$\pi r^2 \left(\frac{0}{6} + 0\right) + c = C_0$$

$$\therefore c = C_0$$

$$\therefore C(h) = \pi r^2 \left(\frac{h^3 + 24h}{6}\right) + C_0$$

8 $y = \sin x$, $0 \leq x \leq \pi$

$$\therefore \frac{dy}{dx} = \cos x$$

$$\therefore L = \int_0^\pi \sqrt{1 + \cos^2 x} dx \approx 3.82020 \text{ units} \quad \{\text{technology}\}$$

- 9 a** The yield Y per unit area A is proportional to $\frac{1}{\sqrt{x+4}}$.

$$\therefore \frac{dY}{dA} \propto \frac{1}{\sqrt{x+4}}$$

$$\therefore \frac{dY}{dA} = \frac{k}{\sqrt{x+4}} \quad \text{for some constant } k.$$

- b** The shaded area $A = \text{length} \times \text{width}$

$$\therefore A = (4 - 2p)x$$

$$\therefore \frac{dA}{dx} = 4 - 2p$$

$$\text{Now } \frac{dY}{dx} = \frac{dY}{dA} \frac{dA}{dx} \quad \{\text{chain rule}\}$$

$$\therefore \frac{dY}{dx} = \frac{k}{\sqrt{x+4}} \times (4 - 2p)$$

$$\therefore \frac{dY}{dx} = \frac{k(4 - 2p)}{\sqrt{x+4}}$$

- c** $\frac{dY}{dx}$ is the instantaneous rate of change of the yield with respect to the distance x from the canal.

$$\therefore \text{total yield} = Y = \int_0^p \frac{dY}{dx} dx = \int_0^p \frac{k(4 - 2p)}{\sqrt{x+4}} dx$$

- d** Using **c**, $Y = k(4 - 2p) \int_0^p (x + 4)^{-\frac{1}{2}} dx$

$$= k(4 - 2p) \times \left[\frac{(x + 4)^{\frac{1}{2}}}{\frac{1}{2}} \right]_0^p$$

$$= 2k(4 - 2p) [\sqrt{x + 4}]_0^p$$

$$= 4k(2 - p) [\sqrt{p + 4} - \sqrt{4}]$$

$$\therefore Y = 4k(2 - p) (\sqrt{p + 4} - 2)$$

- e** Using technology to graph Y and find its maximum, we find that the maximum occurs when $p \approx 0.9735$ km

$\therefore$ the orchard is $0.974 \text{ km} \times 2.05 \text{ km}$.

Let $x = 2 \sin u$, $\frac{dx}{du} = 2 \cos u$

when $x = 0$, $u = 0$

when $x = 2$, $u = \frac{\pi}{2}$

- 7** Since the chord is parallel to the y -axis, the y -coordinate of P is $\frac{r}{2}$.

$$\begin{aligned}
\text{When } y = \frac{r}{2}, \quad x^2 + \left(\frac{r}{2}\right)^2 &= r^2 \\
\therefore x^2 &= \frac{3}{4}r^2 \\

$\therefore$ the coordinates of P are $\left(\frac{\sqrt{3}}{2}r, \frac{r}{2}\right)$.

$$\begin{aligned}

- 8** When $y = 3$, $x^2 + 3^2 = r^2$
 $\therefore x^2 = r^2 - 9$
 $\therefore x = \pm \sqrt{r^2 - 9}$

$\therefore$ the coordinates of P are $(\sqrt{r^2 - 9}, 3)$.

$$\begin{aligned}

- 3** $\int_{-1}^3 f(x) dx$ gives us the correct area only if $f(x)$ is non-negative on the interval $-1 \leq x \leq 3$.
 In this case $f(x)$ is negative for $1 < x < 3$, so $\int_{-1}^3 f(x) dx$ does not provide the correct answer.
 (The shaded area which is below the x -axis is given by $\int_1^3 [0 - f(x)] dx = -\int_1^3 f(x) dx$.
 $\therefore$ total area shaded $= \int_{-1}^1 f(x) dx - \int_1^3 f(x) dx$)

$$\text{4 } y = k \text{ meets } y = x^2 \text{ where } x^2 = k \quad \therefore x = \pm\sqrt{k}$$

$$\therefore \left[kx - \frac{x^3}{3} \right]_0^{\sqrt{k}} = \frac{8}{3}$$

$$\therefore k\sqrt{k} - \frac{k\sqrt{k}}{3} = \frac{8}{3}$$

$$\therefore \frac{2}{3}k\sqrt{k} = \frac{8}{3}$$

$$\therefore k\sqrt{k} = 4$$

$$\therefore k^{\frac{3}{2}} = 4$$

$$\therefore k = 4^{\frac{2}{3}} = \sqrt[3]{16}$$

$y = e^x$ and $y = \ln x$ are inverse functions, so they are symmetrical about $y = x$

$\therefore \text{area } A = \text{area } A'$

But $\text{area } A' + \text{area } B = \text{area of rectangle}$

$\therefore \text{area } A + \text{area } B = e \times 1 = e$

Since $\text{area } A = \int_1^e \ln x \, dx$

and $\text{area } B = \int_0^1 e^x \, dx,$

$\int_0^1 e^x \, dx + \int_1^e \ln x \, dx = e$

6 $y = x^2 + 4x + 1$ meets $y = 3x + 3$ where $x^2 + 4x + 1 = 3x + 3$

$\therefore (x + 2)(x - 1) = 0$

7 Consider $y = 4e^x - 1$.

The x -intercept occurs when $y = 0$

$\therefore 4e^x - 1 = 0$

$\therefore e^x = \frac{1}{4}$

$\therefore x = \ln \frac{1}{4} < 0$

$y = 4e^x - 1$ is the graph of $y = e^x$ with a vertical stretch of factor 4 and a vertical translation of -1 .

Area $= \int_{\ln \frac{1}{4}}^0 (4e^x - 1) \, dx$

$$\begin{aligned}\text{b Now } s(t) &= \int (t^2 - 6t + 8) dt \\ &= \frac{t^3}{3} - 3t^2 + 8t + c\end{aligned}$$

$$\therefore s(0) = c$$

$$s(2) = c + 6\frac{2}{3}$$

$$s(4) = c + 5\frac{1}{3}$$

$$s(5) = c + 6\frac{2}{3}$$

the motion diagram is:

The particle moves in the positive direction initially, then at $t = 2$, $6\frac{2}{3}$ m from its starting point, it changes direction. It changes direction again at $t = 4$, $5\frac{1}{3}$ m from its starting point. When $t = 5$ it is $6\frac{2}{3}$ m from its starting point.

c After 5 seconds, the particle is $6\frac{2}{3}$ m to the right of its starting point.

$$\begin{aligned}\text{d The total distance travelled} &= (c + \frac{20}{3} - c) + [(c + \frac{20}{3}) - (c + \frac{16}{3})] + [(c + \frac{20}{3}) - (c + \frac{16}{3})] \\ &= 9\frac{1}{3} \text{ m}\end{aligned}$$

$$10 \quad \frac{d^2y}{dx^2} = k(L-x)^2$$

$$\therefore \frac{dy}{dx} = \int k(L-x)^2 dx = \frac{-k(L-x)^3}{3} + c$$

But when $x = 0$ the tangent is horizontal and so $\frac{dy}{dx} = 0$.

$$\therefore \frac{-kL^3}{3} + c = 0 \quad \text{and so} \quad c = \frac{kL^3}{3}$$

$$\therefore \frac{dy}{dx} = \frac{-k(L-x)^3}{3} + \frac{kL^3}{3}$$

$$\begin{aligned} \therefore y &= \int \left(\frac{-k(L-x)^3}{3} + \frac{kL^3}{3} \right) dx \\ &= \frac{k(L-x)^4}{12} + \frac{kL^3}{3}x + d \end{aligned}$$

$$\text{But when } x = 0, y = 0 \quad \therefore \frac{kL^4}{12} + d = 0$$

$$\therefore d = -\frac{kL^4}{12}$$

$$\therefore y = \frac{k(L-x)^4}{12} + \frac{kL^3x}{3} - \frac{kL^4}{12}$$

The greatest deflection occurs when $x \approx L$

$$\therefore y \approx \frac{k(0)^4}{12} + \frac{kL^4}{3} - \frac{kL^4}{12} = \frac{kL^4}{4}$$

$\therefore$ the greatest deflection is about $\frac{kL^4}{4}$ metres.

$$11 \quad \text{a} \quad \text{The shaded area} = \int_0^2 ax(x-2) dx = 4 \text{ units}^2$$

$$\therefore \int_0^2 (ax^2 - 2ax) dx = 4$$

$$\therefore \left[\frac{ax^3}{3} - ax^2 \right]_0^2 = 4$$

$$\therefore \left(\frac{8a}{3} - 4a \right) - 0 = 4$$

$$\therefore \frac{8a}{3} - \frac{12a}{3} = 4$$

$$\therefore -\frac{4a}{3} = 4$$

$$\therefore a = -3$$

$$\therefore y = -3x(x-2)$$

$$\text{b} \quad \text{Suppose A has coordinates } (k, -3k(k-2)).$$

$$\begin{aligned} \therefore \text{gradient of [OA]} &= \frac{-3k(k-2) - 0}{k - 0} \\ &= -3(k-2) \end{aligned}$$

$$\therefore \text{equation of [OA] is } y = -3(k-2)x$$

If [OA] divides the shaded region into equal areas,

$$\int_0^k [-3x(x-2) - (-3(k-2)x)] dx = 2$$

$$\therefore \int_0^k (-3x^2 + 6x + 3kx - 6x) dx = 2$$

$$\therefore \int_0^k (-3x^2 + 3kx) dx = 2$$

$$\therefore \left[-x^3 + \frac{3kx^2}{2} \right]_0^k = 2$$

$$\therefore -k^3 + \frac{3k^3}{2} = 2$$

$$\therefore \frac{k^3}{2} = 2$$

$$\therefore k^3 = 4$$

$$\therefore k = \sqrt[3]{4}$$

$\therefore$ the x -coordinate of A is $\sqrt[3]{4}$.

- 12 a** A is the *upper half* of a circle centre $(2, 0)$ and radius 2.

$$\therefore (x - 2)^2 + (y - 0)^2 = 2^2$$

$$(x - 2)^2 + y^2 = 4$$

$$y^2 = 4 - (x - 2)^2$$

$$y^2 = 4 - x^2 + 4x - 4$$

$$y^2 = 4x - x^2$$

$$\therefore y = \pm \sqrt{4x - x^2}$$

$$\text{So, } y = \sqrt{4x - x^2}$$

$$\text{or } y = -\sqrt{4x - x^2}$$

Since A is the upper half of the circle,

$$y_A = \sqrt{4x - x^2}$$

- b** Now B is the *lower half* of a circle centre $(5, 0)$ and radius 1.

$$\therefore (x - 5)^2 + (y - 0)^2 = 1^2$$

$$(x - 5)^2 + y^2 = 1$$

$$y^2 = 1 - (x - 5)^2$$

$$y^2 = 1 - x^2 + 10x - 25$$

$$\therefore y = \pm \sqrt{10x - x^2 - 24}$$

$$\therefore y_B = -\sqrt{10x - x^2 - 24}$$

$$\begin{aligned} \mathbf{c} \quad & \int_0^4 y_A \, dx \\ &= \frac{1}{2} \pi r^2 \text{ where } r = 2 \\ &= \frac{1}{2} \pi (2)^2 \\ &= 2\pi \end{aligned}$$

13 a $V = \frac{1}{3}\pi r^2 h$

$$= \frac{1}{3}\pi \times 4^2 \times 8$$

$$= \frac{1}{3}\pi \times 128$$

$$= \frac{128\pi}{3} \text{ units}^3$$

b

$$\text{gradient} = \frac{0-4}{8-0} = -\frac{1}{2}$$

$$\therefore \text{the line has equation } y = -\frac{1}{2}x + 4$$

$$\therefore V = \pi \int_0^8 \left(-\frac{1}{2}x + 4\right)^2 dx$$

$$= \pi \int_0^8 \left(\frac{x^2}{4} - 4x + 16\right) dx$$

$$= \pi \left[\frac{x^3}{12} - \frac{4x^2}{2} + 16x \right]_0^8$$

$$= \pi \left(\frac{128}{3} - 128 + 128 - 0 \right)$$

$$= \frac{128\pi}{3} \text{ units}^3 \quad \checkmark$$

14 a $\frac{d}{dx} [\ln(\tan x + \sec x)] = \frac{\sec^2 x + \sec x \tan x}{\tan x + \sec x}$

$$= \sec x$$

$$\therefore \int \sec x \, dx = \ln |\tan x + \sec x| + c$$

b

i

ii $y = \sec(2x)$ and $y = 3$ meet when $\sec(2x) = 3$

$$\therefore \cos(2x) = \frac{1}{3}$$

$$\therefore x^* \approx 0.615 \quad \{\text{see the graph}\}$$

$$\begin{aligned}
 \therefore \text{shaded area} &\approx (\text{rectangle area}) - \int_0^{0.615} \sec(2x) \, dx \\
 &\approx 0.615 \times 3 - \left[\frac{1}{2} \ln |\tan(2x) + \sec(2x)| \right]_0^{0.615} \\
 &\approx 1.846 - \left[\frac{1}{2} \ln |\tan(1.23) + \sec(1.23)| - \frac{1}{2} \ln |0 + 1| \right] \\
 &\approx 0.965 \text{ units}^2
 \end{aligned}$$

15 $y = \sin x$ and $y = \cos x$
meet where $\sin x = \cos x$
 $\therefore \frac{\sin x}{\cos x} = 1$
 $\therefore \tan x = 1$
 $\therefore x = \frac{\pi}{4}$

Hence $V = \pi \int_0^{\frac{\pi}{4}} (\cos^2 x - \sin^2 x) \, dx$
 $= \pi \int_0^{\frac{\pi}{4}} \cos(2x) \, dx$
 $= \pi \left[\frac{1}{2} \sin(2x) \right]_0^{\frac{\pi}{4}}$

 $= \pi \left(\frac{1}{2}(1) - 0 \right)$
 $= \frac{\pi}{2} \text{ units}^3$

Now $x^3 = y$
 $\therefore (x^3)^{\frac{2}{3}} = y^{\frac{2}{3}}$
 $\therefore x^2 = y^{\frac{2}{3}}$
Volume $V = \pi \int_0^8 x^2 \, dy$
 $= \pi \int_0^8 y^{\frac{2}{3}} \, dy$
 $= \pi \left[\frac{y^{\frac{5}{3}}}{\frac{5}{3}} \right]_0^8$
 $= \frac{3\pi}{5} \left(8^{\frac{5}{3}} - 0^{\frac{5}{3}} \right)$
 $= \frac{3\pi}{5} \times (2^3)^{\frac{5}{3}}$
 $= \frac{3\pi}{5} \times 2^5$
 $= \frac{96\pi}{5} \text{ units}^3$

Chapter 23

DESCRIPTIVE STATISTICS

EXERCISE 23A

- 1 a Heights can take any value from 170 cm to 205 cm, including decimal values such as 181.37 cm. The ‘height’ variable can take any real number between 170 and 205.

- c The modal class is the class occurring most often. This is $185 \leq H < 190$ cm.
- d The distribution is slightly positively skewed, as there is more of a ‘tail’ to the right.

- 2 a The data is continuous numerical. Actual time is continuous and could be measured to the nearest second, millisecond, and so on. After it has been rounded to the nearest minute, it becomes discrete numerical data.
- c The distribution is positively skewed, or skewed to the high end.

b

Time (min)	Tally	Frequency
0 - 9		6
10 - 19		26
20 - 29		13
30 - 39		9
40 - 49		6

- d The travelling time modal class is 10 - 19 min, if considering classes. (The mode is actually 10, as 10 occurs most frequently.)

- 3 a The data is discrete numerical, so a column graph should be used.

- b The data is continuous, so a frequency histogram should be used.

- 4 a Number which are ≥ 400 mm is $14 + 6 = 20$ seedlings.
- b $12 + 18 + 42 + 28 + 14 + 6 = 120$ seedlings have been sampled.

$$\begin{aligned} \therefore \% \text{ between } 349 \text{ and } 400 &= \frac{42 + 28}{120} \times 100\% \\ &= \frac{70}{120} \times 100\% \\ &\approx 58.3\% \end{aligned}$$

- c i Number less than 400 mm
- $$\begin{aligned} &= \frac{12 + 18 + 42 + 28}{120} \times 1462 \\ &= \frac{100}{120} \times 1462 \\ &\approx 1218 \text{ seedlings} \end{aligned}$$

- ii Number between 374 mm and 425 mm
- $$\begin{aligned} &= \frac{28 + 14}{120} \times 1462 \\ &= \frac{42}{120} \times 1462 \\ &\approx 512 \text{ seedlings} \end{aligned}$$

- 2 a** mean of set A = $\frac{3 + 4 + 4 + 5 + \dots + 10}{13}$
 ≈ 6.46

mean of set B = $\frac{3 + 4 + 4 + 5 + \dots + 15}{13}$
 ≈ 6.85

b median of set A = 7th score = 7 median of set B = 7th score = 7

c The data sets are the same except for the last value, and the last value of set A is less than that of set B. So, the mean of set A is less than that of set B.

d The middle value of both data sets is the same, so the median is the same.
- 3 a** $\text{mean} = \frac{23\,000 + 46\,000 + 23\,000 + \dots + 32\,000}{10} = \$29\,300$

median = middle score when in order of size = $\frac{\$23\,000 + \$24\,000}{2} = \$23\,500$

mode = \$23 000

b The mode is unsatisfactory because it is the lowest salary. It does not take the higher values into account.

c The median is too close to the lower end of the distribution since the data is positively skewed. So the median is not a satisfactory measure of the middle.
- 4 a** $\text{mean} = \frac{3 + 1 + 0 + 0 + \dots + 1 + 0 + 0}{31} = \frac{99}{31} \approx 3.19$

median = 16th score (when in order) = 0

mode = 0 (most frequently occurring score)

b The median is not in the centre, as the data is very positively skewed.

c The mode is the lowest value. It does not take the higher values into account.

d Yes, 21 and 42. **e** No, as this would ignore actual valid data.
- 5 a** $\text{mean} = \frac{43 + 55 + 41 + 37}{4} = \frac{176}{4} = 44$ points

b another 44 points

c i new mean = $\frac{176 + 25}{5} = 40.2$ points

ii It will increase the new mean to 40.3 points as 41 points is greater than the old mean of 40.2 points.

$\left\{ \frac{5 \times 40.2 + 41}{6} \approx 40.3 \right\}$
- 6** $\text{mean} = \frac{\text{total}}{12} \quad \therefore \quad \$15\,467 = \frac{\text{total}}{12} \quad \therefore \quad \text{total} = \$15\,467 \times 12 = \$185\,604$

$$7 \quad \text{mean} = \frac{\text{total}}{12} \quad \therefore 262 = \frac{\text{total}}{12} \quad \therefore \text{total} = 262 \times 12 = 3144 \text{ km}$$

$$8 \quad \text{a} \quad \text{mean birth mass} = \frac{75 + 70 + 80 + \dots + 83}{8} = \frac{567}{8} \approx 70.9 \text{ grams}$$

$$\text{b} \quad \text{mean after 2 weeks} = \frac{210 + 200 + 200 + \dots + 230}{8} = \frac{1681}{8} \approx 210 \text{ grams}$$

$$\text{c} \quad \text{mean increase} \approx (210.13 - 70.88) \text{ grams} \approx 139 \text{ grams}$$

$$9 \quad \mu = \frac{\sum_{i=1}^n x_i}{n} \quad \therefore 11.6 = \frac{\sum_{i=1}^{10} x_i}{10} \quad \therefore \sum_{i=1}^{10} x_i = 11.6 \times 10 = 116$$

$$10 \quad \text{Total for first 14 matches} = 14 \times 16.5 \text{ goals} = 231 \text{ goals}$$

$$\therefore \text{new average} = \frac{231 + 21 + 24}{16} = \frac{276}{16} = 17.25 \text{ goals per game}$$

$$11 \quad \text{a} \quad \text{mean selling price} = \frac{146\,400 + 127\,600 + 211\,000 + \dots + 162\,500}{10} = \$163\,770$$

$$\text{median selling price} = \frac{5\text{th} + 6\text{th}}{2} = \frac{146\,400 + 148\,000}{2} = \$147\,200$$

These figures differ by \$16 570. There are more selling prices at the lower end of the market.

- b**
- i** Use the mean as it tends to inflate the average house value of that district.
 - ii** Use the median as you want to buy at the lowest price possible.

$$12 \quad \frac{5 + 9 + 11 + 12 + 13 + 14 + 17 + x}{8} = 12$$

$$\therefore \frac{81 + x}{8} = 12$$

$$\therefore 81 + x = 96$$

$$\therefore x = 15$$

$$13 \quad \frac{3 + 0 + a + a + 4 + a + 6 + a + 3}{9} = 4$$

$$\therefore \frac{4a + 16}{9} = 4$$

$$\therefore 4a + 16 = 36$$

$$\therefore 4a = 20$$

$$\therefore a = 5$$

$$14 \quad \frac{29 + 36 + 32 + 38 + 35 + 34 + 39 + x}{8} = 35$$

$$\therefore \frac{243 + x}{8} = 35$$

$$\therefore 243 + x = 280$$

$$\therefore x = 37$$

So, her 8th result was 37.

$$15 \quad \text{Total for first 10 measurements} = 10 \times 15.7 = 157$$

$$\text{Total for next 20 measurements} = 20 \times 14.3 = 286$$

$$\therefore \text{mean} = \frac{157 + 286}{30} \approx 14.8$$

- 16** If there are 9 measurements with a median of 12, then 12 must be one of the unknown measurements. So, the measurements are 7, 9, 11, 12, 13, 14, 17, 19, and a .

$$\text{mean} = \frac{7 + 9 + 11 + 12 + 13 + 14 + 17 + 19 + a}{9} = \frac{102 + a}{9}$$

$$\therefore \frac{102 + a}{9} = 12$$

$$\therefore 102 + a = 108$$

$$\therefore a = 6$$

So, the other measurements are 6 and 12.

17 Scores were 5 7 9 9 10 a b where $a \leq b$ say.

mean = $\frac{5 + 7 + 9 + 9 + 10 + a + b}{7} = 8$
 $\therefore \frac{40 + a + b}{7} = 8$
 $\therefore 40 + a + b = 56$
 $\therefore a + b = 16 \quad \{a \leq 12, b \leq 12\}$

- If the mode is 6 then one of the unknown numbers must be 6.
Suppose the other unknown number is x .
$$\therefore \frac{4 + 6 + 9 + 6 + 3 + x}{6} = 6$$
$$\therefore 28 + x = 36$$
$$\therefore x = 8$$

Since $a > b$, $a = 8$ and $b = 6$.

3 a We first organise the data into tables:

Girls:

Time x (s)	f	fx

34	3	102
35	5	175
36	4	144
37	4	148

Boys:

33	4	132
34	5	170
35	6	210
36	3	108
37	1	37
Total	20	689

Both boys and girls have 20 member squads, so the median is the average of the 10th and 11th swimmer.

Girls:

$$\begin{aligned}\text{median} &= \frac{36 + 36}{2} \\ &= 36 \text{ s} \\ \text{mean} &= \frac{\sum fx}{\sum f} \\ &= \frac{720}{20} \\ &= 36 \text{ s}\end{aligned}$$

Boys:

$$\begin{aligned}\text{median} &= \frac{34 + 35}{2} \\ &= 34.5 \text{ s} \\ \text{mean} &= \frac{\sum fx}{\sum f} \\ &= \frac{689}{20} \\ &= 34.45 \text{ s}\end{aligned}$$

The tallest column on the *Girls* histogram is the ‘35’ column.
 $\therefore$ the modal class is 34.5 - 35.5 s.

The tallest column on the *Boys* histogram is the ‘35’ column.
 $\therefore$ the modal class is 34.5 - 35.5 s.

So,

Distribution	Girls	Boys
shape	positively skewed	approximately symmetrical
median	36 s	34.5 s
mean	36 s	34.45 s
modal class	34.5 - 35.5 s	34.5 - 35.5 s

b The girls’ distribution is positively skewed and the boys’ distribution is approximately symmetrical. The median and mean swim times for boys are both about 1.5 seconds lower than for girls. Despite this, the distributions have the same modal class because of the skewness in the girls’ distribution. The analysis supports the conjecture that boys generally swim faster than girls with less spread of times.

1 a highest = 97.5 m, lowest = 64.6 m

b The range = $97.5 - 64.6 = 32.9$

So, if intervals of length 5 are used we need about 7 of them.

We choose $60 \leq d < 65$, $65 \leq d < 70$, $70 \leq d < 75$, and so on.

Season ticket holder	1824	779	2603
Not a season ticket holder	3247	1660	4907
Total	5071	2439	7510

- a Total match attendance was 7510.
b i $P(\text{child}) = \frac{2439}{7510} \approx 0.325$ ii $P(\text{not a season ticket holder}) = \frac{4907}{7510} \approx 0.653$
iii $P(\text{adult season ticket holder}) = \frac{1824}{7510} \approx 0.243$

3 We extend the table to include the totals:

	Single	Double	Family	Total
Peak season	125	220	98	443
Off-peak season	248	192	152	592
Total	373	412	250	1035

- a $P(\text{peak season}) = \frac{443}{1035} \approx 0.428$
b $P(\text{single room in the off-peak season}) = \frac{248}{1035} \approx 0.240$
c $P(\text{single room or double room}) = \frac{373+412}{1035} = \frac{785}{1035} \approx 0.758$
d Of the 592 off-peak season bookings, 152 were for family rooms.
 $\therefore P(\text{family room given it was in the off-peak season}) = \frac{152}{592} \approx 0.257$
e $412 + 250 = 662$ bookings were not for a single room. Of these,
 $220 + 98 = 318$ were in the peak season.
 $\therefore P(\text{peak season given it was not a single room}) = \frac{318}{662} \approx 0.480$

10 There are $(n + 7)$ markers in total.

$P(YY) = \frac{3}{13}$
 $\therefore \frac{7}{n+7} \times \frac{6}{n+6} = \frac{3}{13}$
 $\therefore \frac{42}{n^2 + 13n + 42} = \frac{3}{13}$
 $\therefore 546 = 3n^2 + 39n + 126$
 $\therefore 3(n^2 + 13n - 140) = 0$
 $\therefore 3(n - 7)(n + 20) = 0$
 $\therefore n = 7 \quad \{n \geq 0\}$
 $\therefore$ there are 7 blue markers in the bag to start with.

T represents those playing tennis
 N represents those playing netball

$$\therefore \begin{cases} a + b + c + d = 40 \\ a + b = 19 \\ b + c = 20 \\ d = 8 \end{cases}$$

So, $a + b + c = 32$
 $\therefore 19 + c = 32$ and $a + 20 = 32$
 $\therefore c = 13$ and $a = 12$
Hence, $12 + b = 19$

$\therefore 26 + d = 30 \therefore d = 4$
 $24 + c = 26 \therefore c = 2$
and $a + 12 = 24 \therefore a = 12$

- 2 a** $P(2) = 0.1088$ (from table)
- b** Since this is a probability distribution, $\sum P(x_i) = 1$
 $\therefore a + 0.3333 + 0.1088 + 0.0084 + 0.0007 + 0.0000 = 1$
 $\therefore a + 0.4512 = 1$
 $\therefore a = 0.5488$

This is the probability that Jason does not hit a home run in a game.

- c** $P(1) + P(2) + P(3) + P(4) + P(5) = 0.3333 + 0.1088 + 0.0084 + 0.0007 + 0.0000$
 $= 0.4512$

This represents the probability that Jason hits at least one home run in a game.

- e** Jason is most likely to score 0 home runs, so this is the mode of the distribution.
 $p_0 = 0.5488$ Since $p_0 \geq 0.5$, the median is 0 home runs.
- 3 a** Sum of probabilities $\sum P(x_i) = 0.2 + 0.3 + 0.4 + 0.2 = 1.1$
 Since this sum $\neq 1$, this is not a valid probability distribution.
- b** $P(5) = -0.2$, so not all of the probabilities lie in $0 \leq P(x_i) \leq 1$.
 $\therefore$ this is not a valid probability distribution.
- 4 a** The random variable represents the number of hits that Sally has in each game.
 $X = 0, 1, 2, 3, 4$, or 5 .
- b i** $0.07 + 0.14 + k + 0.46 + 0.08 + 0.02 = 1$ {since $\sum_{x=0}^5 P(X = x) = 1$ }

 $\therefore k = 0.23$
- ii** $P(X \geq 2)$

 $= 0.23 + 0.46 + 0.08 + 0.02$
 $= 0.79$
- iii** $P(1 \leq X \leq 3)$
 $= P(1) + P(2) + P(3)$
 $= 0.14 + 0.23 + 0.46$
 $= 0.83$
- c** Sally is most likely to have 3 hits, so this is the mode of the distribution.
 $p = 0.07$
 $p_0 + p_1 = 0.07 + 0.14 = 0.21$
 $p_0 + p_1 + p_2 = 0.21 + 0.23 = 0.44$
 $p_0 + p_1 + p_2 + p_3 = 0.44 + 0.46 = 0.90$
 Since $p_0 + p_1 + p_2 + p_3 \geq 0.5$, the median is 3 hits.

iii The sum of the results for the two rolls is most likely to be 7, so this is the mode.

$$\begin{aligned}

 p_2 + p_3 + p_4 &= \frac{3}{36} + \frac{3}{36} = \frac{6}{36} \\
 p_2 + p_3 + p_4 + p_5 &= \frac{6}{36} + \frac{4}{36} = \frac{10}{36} \\
 p_2 + p_3 + p_4 + p_5 + p_6 &= \frac{10}{36} + \frac{5}{36} = \frac{15}{36} \\
 p_2 + p_3 + p_4 + p_5 + p_6 + p_7 &= \frac{15}{36} + \frac{6}{36} = \frac{21}{36} \approx 0.583
 \end{aligned}$$

Since $p_2 + p_3 + p_4 + p_5 + p_6 + p_7 \approx 0.583 \geq 0.5$, the median is 7.

6 a $P(x) = k(x + 2), \quad x = 1, 2, 3$
 $\therefore P(1) = 3k, \quad P(2) = 4k, \quad P(3) = 5k$

Since this is a probability distribution, $3k + 4k + 5k = 1$

$$\begin{aligned}

 \therefore k &= \frac{1}{12}

 $\therefore P(0) = k, \quad P(1) = \frac{k}{2},$
 $P(2) = \frac{k}{3}, \quad P(3) = \frac{k}{4}$

Since $\sum P(x_i) = 1, \quad k + \frac{k}{2} + \frac{k}{3} + \frac{k}{4} = 1$

$$\therefore \frac{12k + 6k + 4k + 3k}{12} = 1$$

$$\therefore \frac{25k}{12} = 1$$

$$\therefore k = \frac{12}{25}$$

7 a $P(X = x) = k \left(\frac{1}{3}\right)^x \left(\frac{2}{3}\right)^{4-x}, \quad x = 0, 1, 2, 3, 4$

$$P(X = 0) = k \left(\frac{1}{3}\right)^0 \left(\frac{2}{3}\right)^4 = \frac{16k}{81} \approx 0.1975k \qquad P(X = 1) = k \left(\frac{1}{3}\right)^1 \left(\frac{2}{3}\right)^3 = \frac{8k}{81} \approx 0.0988k$$

$$P(X = 2) = k \left(\frac{1}{3}\right)^2 \left(\frac{2}{3}\right)^2 = \frac{4k}{81} \approx 0.0494k \qquad P(X = 3) = k \left(\frac{1}{3}\right)^3 \left(\frac{2}{3}\right)^1 = \frac{2k}{81} \approx 0.0247k$$

$$P(X = 4) = k \left(\frac{1}{3}\right)^4 \left(\frac{2}{3}\right)^0 = \frac{k}{81} \approx 0.0123k$$

b Since $\sum P(X = i) = 1,$

$$\therefore \frac{16k}{81} + \frac{8k}{81} + \frac{4k}{81} + \frac{2k}{81} + \frac{k}{81} = 1$$

$$\therefore \frac{31k}{81} = 1$$

$$\therefore k = \frac{81}{31}$$

$$\therefore k \approx 2.61$$

$$\therefore P(X \geq 2) = P(2) + P(3) + P(4)$$

$$= \frac{4k}{81} + \frac{2k}{81} + \frac{k}{81}$$

$$= \frac{7k}{81}$$

$$= \frac{7}{81} \times \frac{81}{31}$$

$\therefore$ when rolling the dice 180 times, we expect $180 \times \frac{1}{6} = 30$ doubles.

H	\$2
T	−\$1

For playing *once*,

we would expect to win $\frac{1}{2} \times \$2 + \frac{1}{2} \times (-\$1) = \$0.50$

$\therefore$ for 3 games we would expect to win \$1.50.

• The game is fair when the expected gain is 0.

$$\therefore \frac{1}{6}(35 - 7a) = 0$$

$$\therefore 35 - 7a = 0$$

$$\therefore a = 5$$

d If $a = 4$, expected gain $= \frac{1}{6} (35 - 7(4))$
 $= \frac{7}{6}$ dollars

e If $a = 6$, expected gain $= \frac{1}{6} (35 - 7(6))$
 $= -\frac{7}{6}$ dollars

So, the people playing would expect to win about \$1.17 per game, which means the organisers expect to lose \$1.17 per game.

Expectation from 2406 games is $-\frac{7}{6} \times 2406$
 $= -2807$
 $\therefore$ the organisers would expect to gain \$2807.

x	0	1	2	3	4	5	> 5
$P(X = x)$	0.54	0.26	0.15	k	0.01	0.01	0.00

a $0.54 + 0.26 + 0.15 + k + 0.01 + 0.01 = 1$
 $\therefore k + 0.97 = 1$
 $\therefore k = 0.03$

b $\mu = \sum x_i p_i$
 $= 0 \times 0.54 + 1 \times 0.26 + 2 \times 0.15 + 3 \times 0.03 + 4 \times 0.01 + 5 \times 0.01$
 $= 0.26 + 0.30 + 0.09 + 0.04 + 0.05$
 $= 0.74$ So, over a long period the mean number of deaths per dozen crayfish is 0.74.

 ≈ 0.996

x	1	2	3
$P(X = x)$	$\frac{2}{20} = 0.1$	$\frac{6}{20} = 0.3$	$\frac{12}{20} = 0.6$

a The most likely value of X is 3, so this is the mode of the distribution.

b $p_1 = 0.1$
 $p_1 + p_2 = 0.1 + 0.3 = 0.4$
 $p_1 + p_2 + p_3 = 0.4 + 0.6 = 1.0$
Since $p_1 + p_2 + p_3 \geq 0.5$, the median is 3.

c $\mu = \sum x_i p_i$
 $= 1 \times 0.1 + 2 \times 0.3 + 3 \times 0.6$

 $= (0.6)^3$
 $= 0.216$
 $P(3) = \binom{3}{3} (0.4)^3 (0.6)^0$

 $= 0.064$

$P(1) = \binom{3}{1} (0.4)^1 (0.6)^2$

b $\mu = \sum x_i p_i = 0(0.216) + 1(0.432) + 2(0.288) + 3(0.064) = 1.2$
 $\sigma = \sqrt{\sum (x_i - \mu)^2 p_i}$
 $= \sqrt{(0 - 1.2)^2 (0.216) + (1 - 1.2)^2 (0.432) + (2 - 1.2)^2 \times 0.288 + (3 - 1.2)^2 \times 0.064}$
 ≈ 0.849

$$\sigma = \sqrt{\sum (x_i - \mu)^2 p_i}$$
$$\therefore \sigma^2 = \sum (x_i - \mu)^2 p_i$$

$$= (x_1^2 - 2x_1\mu + \mu^2)p_1 + (x_2^2 - 2x_2\mu + \mu^2)p_2 + \dots + (x_n^2 - 2x_n\mu + \mu^2)p_n$$
$$= (x_1^2 p_1 + x_2^2 p_2 + x_3^2 p_3 + \dots + x_n^2 p_n) - 2\mu(x_1 p_1 + x_2 p_2 + \dots + x_n p_n) + \mu^2(p_1 + p_2 + p_3 + \dots + p_n)$$

Now $p_1 + p_2 + \dots + p_n = 1$

$$\therefore \sigma^2 = \sum x_i^2 p_i - 2\mu(\sum x_i p_i) + \mu^2(1)$$
$$= \sum x_i^2 p_i - 2\mu(\mu) + \mu^2 \quad \{\text{since } \sum x_i p_i = \mu\}$$

6 Let X be the payout, so $x = \$20\,000$, $\$8000$, or $\$0$.

$\therefore$ the probability distribution is

x_i	20 000	8000	0
$P(x_i) = p_i$	0.0025	0.03	0.9675

The expectation is $\mu = \sum x_i p_i = 20\,000(0.0025) + 8000(0.03) + 0(0.9675)$

$$= \$290$$

The company expects to pay out \$290 on average in the long run.

$\therefore$ the company should charge $\$290 + \$100 = \$390$.

$$p_1 + p_2 + p_3 + p_4 + p_5 = \frac{16}{36} + \frac{9}{36} = \frac{25}{36} \approx 0.694$$

 $\therefore b = 0.35$

Also, $0.1 + a + 0.3 + b = 1$

a

The binomial distribution applies, as tossing a coin has two possible outcomes (a head or a tail) and each toss is independent of every other toss.

b

The binomial distribution applies, as this is equivalent to tossing one coin 100 times.

- c** The binomial distribution applies as we can draw out a red or a blue marble with the same chances each time.
- d** The binomial distribution does not apply as the result of each draw is dependent upon the results of previous draws.
- e** The binomial distribution does not apply, assuming that ten bolts are drawn without replacement, as we do not have a repetition of independent trials.

5 a Y is a continuous random variable if $5 - 12y \geq 0$ for all $0 \leq y \leq k$ and $\int_0^k (5 - 12y) dy = 1$. Since $f(y) = 5 - 12y$ is a decreasing function, $f(k) = 5 - 12k$ is the smallest value of $f(y)$ on $0 \leq y \leq k$.

$$\begin{aligned}
 & \therefore 5 - 12k \geq 0 \\

7 a If $\int_0^m 2e^{-2x} dx = \frac{1}{2}$
 then $[-e^{-2x}]_0^m = \frac{1}{2}$
 $\therefore -e^{-2m} - (-e^0) = \frac{1}{2}$
 $\therefore \frac{1}{2} = e^{-2m}$
 $\therefore -2m = \ln \frac{1}{2}$
 $\therefore m = -\frac{1}{2} \ln \frac{1}{2} \approx 0.347$

b $f(x) = 2e^{-2x}$
 $\therefore f'(x) = -4e^{-2x}$
 $\therefore f'(x) < 0$ for all $x \geq 0$ $\{e^{-2x} > 0\}$
 $\therefore f(x)$ is always decreasing for $x \geq 0$
 $\therefore$ the mode $= 0$

8 a $\int_0^a 6 \cos 3x dx = 1$
 $\therefore [2 \sin 3x]_0^a = 1$
 $\therefore 2 \sin 3a - 2 \sin 0 = 1$
 $\therefore \sin 3a = \frac{1}{2}$
 $\therefore 3a = \frac{\pi}{6}$
 $\therefore a = \frac{\pi}{18}$

b $\mu = \int_0^{\frac{\pi}{18}} 6x \cos 3x dx$
 We integrate by parts with $u = 6x$ $v' = \cos 3x$
 $u' = 6$ $v = \frac{1}{3} \sin 3x$
 $\therefore \int 6x \cos 3x dx = 2x \sin 3x - \int 2 \sin 3x dx$
 $= 2x \sin 3x + \frac{2}{3} \cos 3x + c$
 $\therefore \mu = \int_0^{\frac{\pi}{18}} 6x \cos 3x dx$
 $= \left[2x \sin 3x + \frac{2}{3} \cos 3x \right]_0^{\frac{\pi}{18}}$
 $= \left(\frac{\pi}{9} \sin \frac{\pi}{6} + \frac{2}{3} \cos \frac{\pi}{6} \right) - \left(0 + \frac{2}{3} \cos 0 \right)$
 $= \frac{\pi}{9} \left(\frac{1}{2} \right) + \frac{2}{3} \left(\frac{\sqrt{3}}{2} \right) - \frac{2}{3}$
 $= \frac{\pi}{18} + \frac{\sqrt{3}-2}{3}$
 ≈ 0.0852

c If k is the 20th percentile of X ,
 then $\int_0^k 6 \cos 3x dx = 0.2$
 $\therefore [2 \sin 3x]_0^k = 0.2$
 $\therefore 2 \sin 3k - 2 \sin 0 = 0.2$
 $\therefore \sin 3k = 0.1$
 $\therefore 3k \approx 0.100$
 $\therefore k \approx 0.0334$

d $E(X^2) = \int_0^{\frac{\pi}{18}} 6x^2 \cos 3x dx$
 ≈ 0.009773 {using technology}
 $\therefore \text{Var}(X) \approx 0.009773 - (0.0852)^2$
 ≈ 0.002511
 $\therefore \sigma_X \approx \sqrt{0.002511}$
 ≈ 0.0501

So, the 20th percentile of $X \approx 0.0334$

9 $P\left(X \leq \frac{2}{3}\right) = \frac{1}{243}$
 $\therefore \int_0^{\frac{2}{3}} ax^4 dx = \frac{1}{243}$
 $\therefore \left[\frac{1}{5}ax^5\right]_0^{\frac{2}{3}} = \frac{1}{243}$
 $\therefore \frac{1}{5}a \times \left(\frac{2}{3}\right)^5 = \frac{1}{243}$
 $\therefore \frac{1}{5}a \times \frac{32}{243} = \frac{1}{243}$
 $\therefore a = \frac{5}{32}$

So, $\int_0^k \frac{5}{32}x^4 dx = 1$
 $\therefore \left[\frac{1}{32}x^5\right]_0^k = 1$
 $\therefore \frac{1}{32}k^5 = 1$
 $\therefore k^5 = 32$
 $\therefore k = 2$

b From the graph in **a**, $f(x) \geq 0$ for all $x \in [0, 0.9]$.

Also, the area under the curve

$$\begin{aligned} &= \int_0^{0.6} \frac{125}{18} x^2 \, dx + \int_{0.6}^{0.9} \frac{9}{10x^2} \, dx \\ &= \left[\frac{125}{54} x^3 \right]_0^{0.6} + \left[-\frac{9}{10x} \right]_{0.6}^{0.9} \\ &= \frac{125}{54} \left(\frac{3}{5} \right)^3 + \left(-\frac{9}{9} \right) - \left(-\frac{9}{6} \right) \\ &= \frac{1}{2} - 1 + \frac{3}{2} \\ &= 1 \quad \text{as required} \end{aligned}$$

c $\mu = \int_0^{0.9} x f(x) \, dx$

d $E(X^2) = \int_0^{0.9} x^2 f(x) \, dx$

$$\begin{aligned} &= \int_0^{0.6} \frac{125}{18} x^4 \, dx + \int_{0.6}^{0.9} \frac{9}{10} \frac{1}{x} \, dx \\ &= \left[\frac{125}{18} x^5 \right]_0^{0.6} + \left[\frac{9}{10} \ln x \right]_{0.6}^{0.9} \\ &= \frac{125}{18} \left(\frac{3}{5} \right)^5 + \frac{9}{10} \left(\frac{9}{10} \right) - \frac{9}{10} \left(\frac{3}{5} \right) \\ &= \frac{189}{500} \\ \therefore \text{Var}(X) &\approx \frac{189}{500} - 0.58992^2 \\ &\approx 0.0300 \\ \therefore \sigma_X &\approx \sqrt{0.029994} \\ &\approx 0.173 \end{aligned}$$

From the calculations in **b**,

$$\int_0^{0.6} f(x) \, dx = \int_{0.6}^{0.9} f(x) \, dx = \frac{1}{2}$$

$\therefore$ median = 0.6

From the graph in **a**, the highest value of $f(x)$ occurs at $x = 0.6$

$\therefore$ mode = 0.6

$P(0.3 < X < 0.7)$

EXERCISE 26B

2 a, b The mean volume (or diameter) is likely to occur most often with variations around the mean occurring symmetrically as a result of random variations in the production process.

- a** $P(\text{value between } \mu - \sigma \text{ and } \mu + \sigma)$
 $\approx 34.13\% + 34.13\%$
 ≈ 0.683
- b** $P(\text{value between } \mu \text{ and } \mu + 2\sigma)$
 $\approx 34.13\% + 13.59\%$
 ≈ 0.477

We need the percentage greater than 189 cm.
This is $13.59\% + 2.15\% + 0.13\%$
 $\approx 15.9\%$

We need the percentage greater than 179 cm.
This is $34.13\% + 34.13\% + 13.59\%$
 $+ 2.15\% + 0.13\%$
 $\approx 84.1\%$

We need the percentage between 174 cm and 199 cm.
This is $13.59\% + 34.13\% + 34.13\%$
 $+ 13.59\% + 2.15\%$
 $\approx 97.6\%$

We need the percentage greater than 199 cm.
This is 0.13%.

The chance of there being less than 42 mm of rain during August is
 $0.13\% + 2.15\% + 13.59\% = 15.87\%$
and 15.87% of 20 = 3.174

So, over a 20 year period, there would be less than 42 mm of rain during August three times.

$2.15\% + 0.13\% = 2.28\%$ of competitors took over 11 minutes,
and 2.28% of 200 = 4.56
So, 5 competitors took longer than 11 minutes.

$0.13\% + 2.15\% + 13.59\% = 15.87\%$ of competitors took less than 10 minutes 15 seconds,
and 15.87% of 200 = 31.74
So, 32 competitors took less than 10 minutes 15 seconds.

$34.13\% + 34.13\% = 68.26\%$ of competitors took between 10 minutes 15 seconds and 10 minutes 45 seconds, and 68.26% of $200 = 136.52$. So, 137 competitors took between 10 minutes 15 seconds and 10 minutes 45 seconds.

$0.13\% + 2.15\% + 13.59\% + 34.13\% + 34.13\% = 84.13\%$ of babies born weighed less than 3.2 kg, and 84.13% of $545 = 458.5085$. So, 459 babies born weighed less than 3.2 kg.

$34.13\% + 34.13\% + 13.59\% = 81.85\%$ of babies born weighed between 2.8 kg and 3.4 kg, and 81.85% of $545 = 446.0825$. So, 446 babies born weighed between 2.8 kg and 3.4 kg.

- a** $P(\text{value is within 2 standard deviations of the mean})$
 $= P(2.8 \leq X \leq 3.2)$
 $\approx 13.59\% + 34.13\% + 34.13\% + 13.59\%$
 ≈ 0.954
- b** The value 1 standard deviation below the mean is $X = 3 - 0.1 = 2.9$

84% of the crop weigh more than 152 g $\therefore \mu - \sigma = 152$
16% of the crop weigh more than 200 g $\therefore \mu + \sigma = 200$ (1)
Adding: $2\mu = 352$, and so $\mu = 176$ g
Substituting $\mu = 176$ into (1) gives $\sigma = 200 - \mu = 24$ g.

- b** For $\mu = 176$ g and $\sigma = 24$ g, 152 g $= \mu - \sigma$, and 224 g $= \mu + 2\sigma$.
 $\therefore$ between 152 g and 224 g, the percentage is $34.13\% + 34.13\% + 13.59\% \approx 81.9\%$

- a**
- i** $P(162 < X < 170) \approx 34.1\%$
- ii** $P(170 < X < 186) \approx 34.13\% + 13.59\% \approx 47.7\%$
- b**
- i** $P(178 < X < 186)$
 $\approx 13.59\%$
 ≈ 0.136
- ii** $P(X < 162)$
 $\approx 1 - (0.5 + 0.3413)$
 ≈ 0.159
- iii** $P(X < 154)$
 $\approx 0.0215 + 0.0013$
 ≈ 0.0228
- iv** $P(X > 162)$
 $\approx 1 - 0.159$ {using **b ii**}
 ≈ 0.841
- c** 16% of students are taller than 178 cm {13.59% + 2.15% + 0.13% $\approx$ 16%}
 $\therefore k = 178$

11

- a** 97.72% of 13 year old boys are taller than 131 cm $\therefore \mu - 2\sigma = 131$
 2.28% of 13 year old boys are taller than 179 cm $\therefore \mu + 2\sigma = 179$ (1)
- $$\text{Adding:} \quad \frac{2\mu}{\quad} = 310, \quad \text{and so } \mu = 155 \text{ cm}$$
- Substituting $\mu = 155 \text{ cm}$ into (1) gives $\sigma = \frac{179 - \mu}{2} = \frac{24}{2} = 12 \text{ cm}$
- b** For $\mu = 155 \text{ cm}$ and $\sigma = 12 \text{ cm}$, $143 \text{ cm} = \mu - \sigma$, and $191 \text{ cm} = \mu + 3\sigma$
 $\therefore$ between 143 cm and 191 cm, the percentage is $34.13\% + 34.13\% + 13.59\% + 2.15\% \approx 84.0\%$
 So the probability is 0.84.

12 Without fertiliser

- a** $P(\text{without and } < 50)$
 $\approx 50\% + 34.13\%$
 $\approx 84.1\%$
- c** **i** $P(\text{with and } 20 \leq X \leq 60)$
 $\approx 2.15\%$
- d** **i** $P(\text{with and } X \geq 60)$
 $\approx 13.59\% + 34.13\% + 50\%$
 $\approx 97.7\%$

With fertiliser

- b** $P(\text{with and } < 60)$
 $\approx 0.13\% + 2.15\%$
 $\approx 2.28\%$
- ii** $P(\text{without and } 20 \leq X \leq 60)$
 $\approx 2(34.13\% + 13.59\%)$
 $\approx 95.4\%$
- ii** $P(\text{without and } X \geq 60)$
 $\approx 2.15\% + 0.13\%$
 $\approx 2.28\%$

13

- a** $P(X < 18\,000)$
 $\approx 1 - 0.5 - 0.3413$
 ≈ 0.1587
 $\therefore$ we expect that less than 18 000 bottles
are filled on $260 \times 0.1587 \approx 41$ days.

b $P(X > 16\,000)$
 $\approx 0.1359 + 0.3413 + 0.5$
 ≈ 0.9772
 $\therefore$ we expect that over 16 000 bottles are
filled on $260 \times 0.9772 \approx 254$ days.

c $P(18\,000 \leq X \leq 24\,000)$
 $\approx 0.3413 \times 2 + 0.1359$
 ≈ 0.8185
 $\therefore$ we expect that between 18 000 and 24 000
bottles are filled on 260×0.8185
 ≈ 213 days.

EXERCISE 26C

- 3** If X is the length of a bolt in cm, then X is normally distributed with $\mu = 19.8$ and $\sigma = 0.3$.
 $\therefore P(19.7 < X < 20) \approx 0.378$
- 4** If X is the money collected in dollars, then X is normally distributed with $\mu = 40$ and $\sigma = 6$.
a $P(30.00 < X < 50.00) \approx 0.904$
 $\approx 90.4\%$
b $P(X \geq 50) \approx 0.0478$
 $\approx 4.78\%$
- 5** If X is the length of an eel in cm, then X is normally distributed with $\mu = 41$ and $\sigma = \sqrt{11}$.
a $P(X \geq 50) \approx 0.003\,33$
b $P(40 \leq X \leq 50) \approx 0.615$
 $\approx 61.5\%$
c $P(X \geq 45) \approx 0.114$
So, we would expect $200 \times 0.114 \approx 23$ eels to be at least 45 cm long.
- 6** If X is the speed of a car in km h^{-1} then X is normally distributed with $\mu = 56.3$ and $\sigma = 7.4$.
a $P(60 < X < 75) \approx 0.303$ **b** $P(X \leq 70) \approx 0.968$ **c** $P(X \geq 60) \approx 0.309$
- 7** If X is the weight of an apple in grams, then X is normally distributed with $\mu = 173$ and $\sigma = 34$.
a  $P(X < 130) \approx 0.102\,988\,39$
 ≈ 0.103
So, 10.3% of the apples from this crop were too small to sell.

- b** The chance of one apple being too small to sell is 0.102 988 39 .
 $\therefore$ the distribution is $B(100, 0.102\,988\,39)$
 $\therefore P(X \leq 10) \approx 0.544$
 So, the probability that up to 10 apples were too small to sell is 0.544 .

8

If X is the drop in blood pressure (in units) then X is normally distributed with $\mu = 5.9$ and $\sigma = 1.9$

- a** $P(X \geq 4) \approx 0.841\,344\,74$
 So, 84.1% of people show a drop of more than 4 units.

- b** The chance of one person showing a drop of more than 4 units is 0.841 344 74 .
 $\therefore$ the distribution is $B(8, 0.841\,344\,74)$
 $\therefore P(X > 5) = P(X \geq 6)$
 ≈ 0.880
 So, the probability that more than 5 people show a drop of more than 4 units is 0.880 .

EXERCISE 26E.2

- 1** Let the mean IQ of a student at school be μ .
If X is the IQ of a student at the school, then $X \sim N(\mu, 15^2)$.

$$\text{Now, } P(X \geq 125) = 0.2$$

$$\therefore P\left(\frac{X - \mu}{15} \geq \frac{125 - \mu}{15}\right) = 0.2$$

$$\therefore P\left(Z \geq \frac{125 - \mu}{15}\right) = 0.2$$

$$\therefore P\left(Z < \frac{125 - \mu}{15}\right) = 0.8$$

$$\therefore \frac{125 - \mu}{15} \approx 0.8416$$

$$\therefore \mu \approx 112.4$$

The mean IQ at the school is 112.4.

- 3** Let the standard deviation of the weekly income be σ .
If X denotes the weekly income of the bakery, then $X \sim N(6100, \sigma^2)$.

$$\text{Now, } P(X \geq 6000) = 0.85$$

$$\therefore P\left(Z \geq \frac{6000 - 6100}{\sigma}\right) = 0.85$$

$$\therefore P\left(Z < \frac{6000 - 6100}{\sigma}\right) = 0.15$$

Using invNorm for $N(0, 1^2)$,

$$\frac{-100}{\sigma} \approx -1.0364334$$

$$\therefore \sigma \approx \frac{-100}{-1.0364334}$$

$$\therefore \sigma \approx 96.5$$

So, the standard deviation is \$96.50.

- 5** $X \sim N(\mu, \sigma^2)$ where we have to find μ and σ .

We start by finding z_1 and z_2 which correspond to $x_1 = 35$ and $x_2 = 8$.

$$\text{Now } P(X \geq 35) = 0.32$$

$$\therefore P(X < 35) = 0.68$$

$$\therefore P\left(\frac{X - \mu}{\sigma} < \frac{35 - \mu}{\sigma}\right) = 0.68$$

$$\therefore P\left(Z < \frac{35 - \mu}{\sigma}\right) = 0.68$$

$$\therefore z_1 = \frac{35 - \mu}{\sigma} \approx 0.4677$$

$$\therefore 35 - \mu \approx 0.4677\sigma \quad \dots (1)$$

Solving (1) and (2) simultaneously we get $\mu \approx 23.6$ and $\sigma \approx 24.3$.

- 2** Let the standard deviation of the distances jumped be σ m.

If X is the distance jumped by the athlete, then $X \sim N(5.2, \sigma^2)$.

$$\text{Now, } P(X < 5) = 0.15$$

$$\therefore P\left(\frac{X - 5.2}{\sigma} < \frac{5 - 5.2}{\sigma}\right) = 0.15$$

$$\therefore P\left(Z < -\frac{0.2}{\sigma}\right) = 0.15$$

$$\therefore -\frac{0.2}{\sigma} \approx -1.036$$

$$\therefore \sigma \approx 0.193$$

So, the standard deviation of the distances jumped is 0.193 m.

- 4** Let the mean arrival time be μ minutes after midday.

If X denotes the arrival time of a bus, then $X \sim N(\mu, 5^2)$.

$$\text{Now, } P(X \leq 235) = 0.1$$

{3:55 pm = $3 \times 60 + 55 = 235$ minutes after midday}

$$\therefore P\left(Z \leq \frac{235 - \mu}{5}\right) = 0.1$$

Using invNorm for $N(0, 1^2)$,

$$\frac{235 - \mu}{5} \approx -1.2815516$$

$$\therefore 235 - \mu \approx -6.407758$$

$$\therefore \mu \approx 235 + 6.407758$$

$$\therefore \mu \approx 241.407758 \text{ minutes after midday}$$

and $241.407758 \text{ minutes} = 4 \text{ h } 1 \text{ m } 24 \text{ s}$

So, the mean arrival time of buses at the depot is 4:01:24 pm.

$$\text{and } P(X \leq 8) = 0.26$$

$$\therefore P\left(\frac{X - \mu}{\sigma} \leq \frac{8 - \mu}{\sigma}\right) = 0.26$$

$$\therefore P\left(Z \leq \frac{8 - \mu}{\sigma}\right) = 0.26$$

$$\therefore z_2 = \frac{8 - \mu}{\sigma} \approx -0.6433$$

$$\therefore 8 - \mu \approx -0.6433\sigma \quad \dots (2)$$

- 6 a** $X \sim N(\mu, \sigma^2)$ where we have to find μ and σ .

We start by finding z_1 and z_2 which correspond to $x_1 = 30$ and $x_2 = 80$.

$$\begin{aligned} \text{Now } P(X \leq 30) &= 0.15 & \text{and } P(X \geq 80) &= 0.1 \\ \therefore P\left(\frac{X - \mu}{\sigma} \leq \frac{30 - \mu}{\sigma}\right) &= 0.15 & \therefore P(X < 80) &= 0.9 \\ \therefore P\left(Z \leq \frac{30 - \mu}{\sigma}\right) &= 0.15 & \therefore P\left(\frac{X - \mu}{\sigma} < \frac{80 - \mu}{\sigma}\right) &= 0.9 \\ \therefore z_1 = \frac{30 - \mu}{\sigma} &\approx -1.0364 & \therefore P\left(Z < \frac{80 - \mu}{\sigma}\right) &= 0.9 \\ \therefore 30 - \mu &\approx -1.0364\sigma \dots (1) & \therefore z_2 = \frac{80 - \mu}{\sigma} &\approx 1.2816 \\ & & \therefore 80 - \mu &\approx 1.2816\sigma \dots (2) \end{aligned}$$

Solving (1) and (2) simultaneously, $\mu \approx 52.36 \approx 52.4$ and $\sigma \approx 21.57 \approx 21.6$.

- b** Let X be the result of the mathematics exam.

X is normally distributed with mean μ and standard deviation σ .

We know that $P(X \geq 80) = 0.1$ and $P(X \leq 30) = 0.15$.

So, from **a**, $\mu \approx 52.4$ and $\sigma \approx 21.6$.

If part marks can be given, $P(X > 50) \approx 0.544$
 $\approx 54.4\%$

So, 54.4% of students scored more than 50.

- 7 a**

$X \sim N(\mu, \sigma^2)$ where we have to find μ and σ .

We find z_1 and z_2 which correspond to $x_1 = 3.994$ and $x_2 = 4.006$

$$\begin{aligned} \text{Now } P(X \leq x_1) &= 0.04 & \text{and } P(X \geq x_2) &= 0.05 \\ \therefore P\left(Z \leq \frac{3.994 - \mu}{\sigma}\right) &= 0.04 & \therefore P\left(Z \leq \frac{4.006 - \mu}{\sigma}\right) &= 0.95 \\ \therefore \frac{3.994 - \mu}{\sigma} &= -1.7506861 & \therefore \frac{4.006 - \mu}{\sigma} &= 1.64485363 \\ \therefore 3.994 - \mu &= -1.7506861\sigma \dots (1) & \therefore 4.006 - \mu &= 1.64485363\sigma \dots (2) \end{aligned}$$

Solving simultaneously, $\mu \approx 4.000187009$ and $\sigma \approx 0.00353404788$

$\therefore \mu \approx 4.00$ cm and $\sigma \approx 0.00353$ cm

- b** From **a**, $\mu \approx 4.000$ and $\sigma \approx 0.003534$

$\therefore X \sim N(4.000, 0.003534^2)$

$\therefore P(3.997 \leq X \leq 4.003) \approx 0.604$

So, the probability that a randomly chosen piston has diameter between 3.997 cm and 4.003 cm is 0.604.

$X \sim N(\mu, \sigma^2)$ where we have to find μ and σ .
We start by finding z_1 and z_2 which correspond to $x_1 = 1.94$ and $x_2 = 2.06$.

Now $P(X < 1.94) = 0.02$

and $P(X > 2.06) = 0.03$

$\therefore P\left(\frac{X - \mu}{\sigma} < \frac{1.94 - \mu}{\sigma}\right) = 0.02$
 $\therefore P\left(Z < \frac{1.94 - \mu}{\sigma}\right) = 0.02$
 $\therefore z_1 = \frac{1.94 - \mu}{\sigma} \approx -2.054$
 $\therefore 1.94 - \mu \approx -2.054\sigma \dots (1)$

$\therefore P\left(\frac{X - \mu}{\sigma} > \frac{2.06 - \mu}{\sigma}\right) = 0.03$
 $\therefore P\left(Z > \frac{2.06 - \mu}{\sigma}\right) = 0.03$
 $\therefore P\left(Z \leq \frac{2.06 - \mu}{\sigma}\right) = 0.97$
 $\therefore z_2 = \frac{2.06 - \mu}{\sigma} \approx 1.881$
 $2.06 - \mu \approx 1.881\sigma \dots (2)$

Solving (1) and (2) simultaneously, we get $\mu \approx 2.00$ cm and $\sigma \approx 0.0305$ cm.

- 8 a** Consider the integral $\int_0^1 \frac{4}{1+x^2} dx$.

$$\text{Let } x = \tan \theta, \quad \frac{dx}{d\theta} = \sec^2 \theta$$

$$\text{When } x = 0, \quad \theta = 0, \quad \text{and when } x = 1, \quad \theta = \frac{\pi}{4}$$

$$\begin{aligned}
 \therefore \int_0^1 \frac{4}{1+x^2} dx &= \int_0^{\frac{\pi}{4}} \frac{4}{1+\tan^2 \theta} \sec^2 \theta d\theta \\
 &= \int_0^{\frac{\pi}{4}} 4 d\theta \quad \{1 + \tan^2 \theta = \sec^2 \theta\} \\
 &= [4\theta]_0^{\frac{\pi}{4}} = \pi \\
 \therefore \int_0^1 \frac{4}{1+x^2} dx &\neq 1, \text{ and so } f(x) \text{ cannot be a probability density function.}

$$\mathbf{b} \quad k f(x) = \begin{cases} \frac{4k}{1+x^2} & \text{for } 0 \leq x \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

For a probability density function,

$$\begin{aligned}
 \int_0^1 \frac{4k}{1+x^2} dx &= 1 \\
 \therefore k \int_0^1 \frac{4}{1+x^2} dx &= 1 \\
 \therefore k(\pi) &= 1 \\
 \therefore k &= \frac{1}{\pi}
 \end{aligned}$$

$$\begin{aligned}
 \mathbf{c} \quad \mu &= \frac{1}{\pi} \int_0^1 \frac{4x}{1+x^2} dx & E(X^2) &= \frac{4}{\pi} \int_0^1 \frac{x^2}{1+x^2} dx \\
 &= \frac{2}{\pi} \int_0^1 \frac{2x}{1+x^2} dx & &= \frac{4}{\pi} \int_0^1 \left(1 - \frac{1}{1+x^2}\right) dx \\
 &= \frac{2}{\pi} [\ln(1+x^2)]_0^1 \quad \{\text{as } 1+x^2 > 0\} & &= \frac{4}{\pi} \int_0^1 1 dx - \frac{4}{\pi} \int_0^1 \frac{1}{1+x^2} dx \\
 &= \frac{2}{\pi} (\ln 2 - \ln 1) & &= \frac{4}{\pi} [x]_0^1 - \frac{4}{\pi} [\arctan x]_0^1 \\
 &= \frac{2}{\pi} \ln 2 & &= \frac{4}{\pi} - \frac{4}{\pi} \times \frac{\pi}{4} \\
 & & &= \frac{4}{\pi} - 1 \\
 \therefore \text{Var}(X) &= E(X^2) - \mu^2 & &= \frac{4}{\pi} - 1 - \left(\frac{2}{\pi} \ln 2\right)^2 \\
 & & &= \frac{4}{\pi} - 1 - \left(\frac{2 \ln 2}{\pi}\right)^2

- 9** If X is the volume of drink in mL, then $X \sim N(376, \sigma^2)$.

$$\begin{aligned}
 \text{Now } P(X < 375) &= 0.023 \\
 \therefore P\left(\frac{X-376}{\sigma} < \frac{375-376}{\sigma}\right) &= 0.023 \\
 \therefore P\left(Z < \frac{-1}{\sigma}\right) &= 0.023 \\
 \therefore -\frac{1}{\sigma} &\approx -1.995 \\
 \therefore \sigma &\approx 0.501

$\therefore$ the standard deviation is 0.501 mL.

- 10** If X is the height of an 18 year old boy, then $X \sim N(187, \sigma^2)$.

$$\begin{aligned}
 \text{Now } P(X > 193) &= 0.15 \\
 \therefore P(X \leq 193) &= 0.85 \\
 \therefore P\left(\frac{X-187}{\sigma} \leq \frac{193-187}{\sigma}\right) &= 0.85 \\
 \therefore P\left(Z \leq \frac{6}{\sigma}\right) &= 0.85 \\
 \therefore \frac{6}{\sigma} &\approx 1.0364 \\
 \therefore \sigma &\approx 5.789
 \end{aligned}$$

So, $P(X > 185) \approx 0.635$

$\therefore$ the probability that two 18 year old boys are taller than 185 cm $\approx 0.635^2 \approx 0.403$

11 a $\int_0^k f(x) \, dx = 1$

$$\therefore \int_0^2 \frac{x}{5} \, dx + \int_2^k \frac{8}{5x^2} \, dx = 1$$
$$\therefore \left[\frac{x^2}{10} \right]_0^2 + \left[-\frac{8}{5x} \right]_2^k = 1$$
$$\therefore \frac{4}{10} + \left(-\frac{8}{5k} \right) - \left(-\frac{8}{10} \right) = 1$$
$$\therefore -\frac{8}{5k} = -\frac{2}{10}$$
$$\therefore 10k = 80$$
$$\therefore k = 8$$

b If m is the median of X , then $\int_0^m f(x) \, dx = \frac{1}{2}$

$$\therefore \text{since } \int_0^2 \frac{x}{5} \, dx < \frac{1}{2},$$
$$\int_0^2 \frac{x}{5} \, dx + \int_2^m \frac{8}{5x^2} \, dx = \frac{1}{2}$$
$$\therefore \frac{4}{10} + \left[-\frac{8}{5x} \right]_2^m = \frac{1}{2}$$
$$\therefore \frac{4}{10} + \left(-\frac{8}{5m} \right) - \left(-\frac{8}{10} \right) = \frac{1}{2}$$
$$\therefore -\frac{8}{5m} = -\frac{7}{10}$$
$$\therefore 35m = 80$$
$$\therefore m = \frac{16}{7}$$
$$\therefore \text{the median is } 2\frac{2}{7}$$

c $\mu = \int_0^8 x f(x) \, dx$

$$= \int_0^2 \frac{x^2}{5} \, dx + \int_2^8 \frac{8}{5x} \, dx$$
$$= \left[\frac{x^3}{15} \right]_0^2 + \left[\frac{8}{5} \ln |x| \right]_2^8$$
$$= \frac{8}{15} + \frac{8}{5} \ln 8 - \frac{8}{5} \ln 2$$
$$\approx 2.75$$

$$E(X^2) = \int_0^8 x^2 f(x) \, dx$$
$$= \int_0^2 \frac{x^3}{5} \, dx + \int_2^8 \frac{8}{5} \, dx$$
$$= \left[\frac{x^4}{20} \right]_0^2 + \left[\frac{8}{5} x \right]_2^8$$
$$= \frac{16}{20} + \frac{64}{5} - \frac{16}{5}$$
$$= \frac{52}{5}$$
$$\therefore \text{Var}(X) = E(X^2) - \mu^2$$
$$\approx \frac{52}{5} - 2.751^2$$
$$\approx 2.83$$

EXERCISE 27A

- 1 a** $(1 - i)^2 = 1 - 2i + i^2 = -2i$
 $\therefore (1 - i)^{4n} = [(1 - i)^2]^{2n} = (-2i)^{2n} = [(-2i)^2]^n = (-4)^n$
- b** $(1 - i)^{16} = (1 - i)^{4 \times 4} = (-4)^4 = 256$ {using $(1 - i)^{4n} = (-4)^n$ }
- c** If $z^{16} = 256$ we have a polynomial with real coefficients.
 From **b**, $1 - i$ is one solution and so $1 + i$ must also be a solution {Theorem of real polynomials}
 Thus $z = 1 \pm i$ are two solutions of $z^{16} = 256$.

- 2** $S_n = n^3 + 2n - 1$
 Now $u_n = S_n - S_{n-1}$, $n > 1$
 $= n^3 + 2n - 1 - [(n-1)^3 + 2(n-1) - 1]$
 $= n^3 + 2n - 1 - [n^3 - 3n^2 + 3n - 1] - 2n + 2 + 1$
 $= n^3 + 2n - 1 - n^3 + 3n^2 - 3n + 1 - 2n + 3$
 $= 3n^2 - 3n + 3$, $n > 1$

and $u_1 = S_1 = 2$

$$\therefore u_1 = 2, u_n = 3n^2 - 3n + 3, n > 1$$

- 3** Consider $\frac{3x-1}{|x+1|} > 2$.

If $x = -1$, LHS is undefined, so $x = -1$ is not a solution.

If $x \neq -1$, $|x+1| > 0$ and so $3x-1 > 2|x+1|$.

So, if $x > -1$, $3x-1 > 2x+2 \quad \therefore x > 3$

if $x < -1$, $3x-1 > -2x-2 \quad \therefore 5x > -1$ and so $x > -\frac{1}{5}$, which is impossible.

Thus, $x > 3$ is the solution.

- 4 a** $z = \frac{-1 + i\sqrt{3}}{4}$ $w = \frac{\sqrt{2} + i\sqrt{2}}{4}$
 $= \frac{1}{2} \left(-\frac{1}{2} + i\frac{\sqrt{3}}{2} \right)$ $= \frac{1}{2} \left(\frac{1}{\sqrt{2}} + i\frac{1}{\sqrt{2}} \right)$
 $= \frac{1}{2} \operatorname{cis} \left(\frac{2\pi}{3} \right)$ $= \frac{1}{2} \operatorname{cis} \left(\frac{\pi}{4} \right)$
 $= \frac{1}{2} \left(\cos \frac{2\pi}{3} + i \sin \frac{2\pi}{3} \right)$ $= \frac{1}{2} \left(\cos \frac{\pi}{4} + i \sin \frac{\pi}{4} \right)$

- b** $zw = \frac{1}{2} \operatorname{cis} \left(\frac{2\pi}{3} \right) \times \frac{1}{2} \operatorname{cis} \left(\frac{\pi}{4} \right)$
 $= \frac{1}{4} \operatorname{cis} \left(\frac{2\pi}{3} + \frac{\pi}{4} \right)$
 $= \frac{1}{4} \operatorname{cis} \left(\frac{11\pi}{12} \right)$
 $= \frac{1}{4} \left(\cos \left(\frac{11\pi}{12} \right) + i \sin \left(\frac{11\pi}{12} \right) \right)$

- c** $zw = \frac{1}{16}(-1 + i\sqrt{3})(\sqrt{2} + i\sqrt{2}) = \frac{1}{16}([-\sqrt{2} - \sqrt{6}] + i[\sqrt{6} - \sqrt{2}])$

Equating real and imaginary parts of zw gives $\cos \left(\frac{11\pi}{12} \right) = \frac{-\sqrt{2}-\sqrt{6}}{4}$ and $\sin \left(\frac{11\pi}{12} \right) = \frac{\sqrt{6}-\sqrt{2}}{4}$.

5 As $y^2 = 4x$, $2y \frac{dy}{dx} = 4$ and so $\frac{dy}{dx} = \frac{2}{y}$.

But the tangent has gradient m , so at the point of contact, $m = \frac{2}{y}$ or $y = \frac{2}{m}$.

So, the y -coordinate of the point of contact is $\frac{2}{m}$.

The x -coordinate of the point of contact is $\frac{y^2}{4} = \frac{4}{m^2} \div 4 = \frac{1}{m^2}$

$\therefore$ the point of contact is $\left(\frac{1}{m^2}, \frac{2}{m}\right)$.

This point lies on $y = mx + c$, so $\frac{2}{m} = m\left(\frac{1}{m^2}\right) + c$

$$\therefore \frac{2}{m} = \frac{1}{m} + c$$

$$\therefore c = \frac{1}{m}$$

6 $\sin^2 x + \sin x - 2 = 0$, $-2\pi \leq x \leq 2\pi$

$$\therefore (\sin x + 2)(\sin x - 1) = 0$$

$$\therefore \sin x = -2 \text{ or } 1$$

$$\therefore \sin x = 1 \quad \{\text{as } -1 \leq \sin x \leq 1\}$$

$$\therefore x = \frac{\pi}{2} + k2\pi, \quad k \in \mathbb{Z}$$

$$\therefore x = -\frac{3\pi}{2} \text{ or } \frac{\pi}{2}$$

7 $f(x) = \ln x$ has inverse $f^{-1}(x) = e^x$.

$g(x) = 3 + x$ has inverse given by $x = 3 + y$

$$\therefore y = x - 3 \quad \text{so} \quad g^{-1}(x) = x - 3.$$

a $f^{-1}(2) \times g^{-1}(2)$
 $= e^2 \times -1$
 $= -e^2$

b $(f \circ g)(x) = f(g(x)) = f(3 + x)$
 $= \ln(3 + x)$

$\therefore$ the inverse of $(f \circ g)(x)$ is $x = \ln(3 + y)$

$$\therefore 3 + y = e^x$$

$$\therefore y = e^x - 3$$

So, $(f \circ g)^{-1}(x) = e^x - 3$

and $(f \circ g)^{-1}(2) = e^2 - 3$

8 $\sin \theta = -\frac{5}{13}$

a $\cos \theta$
 $= \sqrt{1 - \sin^2 \theta}$
 $= \sqrt{1 - \frac{25}{169}}$
 $= \sqrt{\frac{144}{169}}$
 $= \frac{12}{13}$

b $\tan \theta$
 $= \frac{\sin \theta}{\cos \theta}$
 $= -\frac{5}{13} \div \frac{12}{13}$
 $= -\frac{5}{12}$

c $\sin 2\theta$
 $= 2 \sin \theta \cos \theta$
 $= 2 \left(-\frac{5}{13}\right) \left(\frac{12}{13}\right)$
 $= -\frac{120}{169}$

d $\sec 2\theta$
 $= \frac{1}{\cos 2\theta}$
 $= \frac{1}{2 \cos^2 \theta - 1}$
 $= \frac{1}{2 \left(\frac{12}{13}\right)^2 - 1}$
 $= \frac{1}{2 \left(\frac{144}{169}\right) - 1} \times \frac{169}{169}$
 $= \frac{169}{288 - 169}$
 $= \frac{169}{119}$

9 $\sqrt{3} \cos x \csc x + 1 = 0, \quad 0 \leq x \leq 2\pi$

$$\therefore \sqrt{3} \cos x \left(\frac{1}{\sin x} \right) = -1$$

$$\therefore \frac{\cos x}{\sin x} = -\frac{1}{\sqrt{3}}$$

$$\therefore \tan x = -\sqrt{3}$$

$$\therefore x = \frac{2\pi}{3} \text{ or } \frac{5\pi}{3}$$

10 Let X be the number of snails.

$$\mu = \sigma^2 = m \quad \text{and} \quad \sigma = d \quad \therefore m = d^2$$

$$\text{Now } P(X = 8) = \frac{1}{2}P(X = 7)$$

$$\text{where } P(X = x) = \frac{m^x e^{-m}}{x!} = \frac{d^{2x} e^{-d^2}}{x!}$$

$$\therefore \frac{d^{16} e^{-d^2}}{8!} = \frac{1}{2} \frac{d^{14} e^{-d^2}}{7!}$$

$$\frac{d^2}{8} = \frac{1}{2}$$

$$\therefore d = 2 \quad \{\text{as } d > 0\}$$

11

$$\overrightarrow{OA} = \begin{pmatrix} 2-\lambda \\ \lambda-3 \\ 1-\lambda \end{pmatrix} \quad \text{and} \quad \mathbf{v} = \begin{pmatrix} -1 \\ 1 \\ -1 \end{pmatrix}$$

The shortest distance occurs when $\overrightarrow{OA} \bullet \mathbf{v} = 0$

$$\therefore -(2-\lambda) + \lambda - 3 + (-1)(1-\lambda) = 0$$

$$\therefore \lambda - 2 + \lambda - 3 - 1 + \lambda = 0$$

$$\therefore 3\lambda = 6 \quad \therefore \lambda = 2$$

So, the point on L that is nearest the origin is $(0, -1, -1)$.

12 $f'(x) > 0$ and $f''(x) < 0$ for all x

$\therefore f(x)$ is increasing and concave downwards for all x .

a $f(2) = 1$ and $f'(2) = 2$

$\therefore (2, 1)$ lies on the curve and the tangent at this point has gradient 2

$\therefore$ the equation of the tangent is $y = 2x + c$

$$\text{and } 1 = 2(2) + c, \quad \text{so } c = -3$$

$\therefore$ the tangent has equation $y = 2x - 3$.

b

c As $f(x)$ is increasing it has *at most one* zero. But $f(x)$ is also concave downwards for all x , so it always lies below the tangent shown. So, for $x < \frac{3}{2}$, the tangent's y -values are negative and so $f(x)$ is also negative. Thus $f(x)$ has *exactly one* zero.

d From the graph, the x -intercept of $y = f(x)$ lies inside $]\frac{3}{2}, 2[$.

13 P_n is " $2n^3 - 3n^2 + n + 31 \geq 0$ " for $n \in \mathbb{Z}, n \geq -2$.

Proof: (By the principle of mathematical induction)

(1) If $n = -2$, $2(-2)^3 - 3(-2)^2 + (-2) + 31 = -16 - 12 - 2 + 31 = 1$ which is ≥ 0
 $\therefore P_{-2}$ is true.

(2) If P_k is assumed true then $2k^3 - 3k^2 + k + 31 \geq 0$

$$\text{Thus } 2(k+1)^3 - 3(k+1)^2 + (k+1) + 31$$

$$= 2(k^3 + 3k^2 + 3k + 1) - 3(k^2 + 2k + 1) + k + 32$$

$$= [2k^3 - 3k^2 + k + 31] + 6k^2 + 6k + 2 - 6k - 3 + 1$$

$$= \underbrace{[2k^3 - 3k^2 + k + 31]}_{\geq 0 \text{ \{using } P_k\}}} + \underbrace{6k^2}_{\geq 0 \text{ as } k^2 \geq 0 \text{ for all } k}$$

$$\geq 0$$

Thus P_{k+1} is true whenever P_k is true.

$\therefore$ since P_{-2} is true, P_n is true for all $n \in \mathbb{Z}, n \geq -2$ {Principle of mathematical induction}

14 We integrate by parts with $u = \arctan x$ $v' = x$

$$u' = \frac{1}{1+x^2} \quad v = \frac{x^2}{2}$$

$$\begin{aligned} \therefore \int x \arctan x \, dx &= \arctan x \left(\frac{x^2}{2} \right) - \int \frac{x^2}{2(1+x^2)} \, dx \\ &= \frac{1}{2} x^2 \arctan x - \frac{1}{2} \int \frac{1+x^2-1}{1+x^2} \, dx \\ &= \frac{1}{2} x^2 \arctan x - \frac{1}{2} \int \left(1 - \frac{1}{1+x^2} \right) \, dx \\ &= \frac{1}{2} x^2 \arctan x - \frac{x}{2} + \frac{1}{2} \arctan x + c \end{aligned}$$

Check:

$$\begin{aligned} &\frac{d}{dx} \left(\frac{1}{2} x^2 \arctan x - \frac{1}{2} x + \frac{1}{2} \arctan x + c \right) \\ &= x \arctan x + \frac{1}{2} x^2 \left(\frac{1}{1+x^2} \right) - \frac{1}{2} + \frac{1}{2} \left(\frac{1}{1+x^2} \right) + 0 \\ &= x \arctan x + \frac{\frac{1}{2} x^2 - \frac{1}{2} (1+x^2) + \frac{1}{2}}{1+x^2} \\ &= x \arctan x + \frac{0}{1+x^2} \\ &= x \arctan x \quad \checkmark \end{aligned}$$

15 a $\log_2(x^2 - 2x + 1) = 1 + \log_2(x - 1)$

$$\begin{aligned} \therefore \log_2(x-1)^2 - \log_2(x-1) &= 1 \\ \therefore 2\log_2(x-1) - \log_2(x-1) &= 1 \\ \therefore \log_2(x-1) &= 1 \\ \therefore x-1 &= 2^1 \\ \therefore x &= 3 \end{aligned}$$

b $3^{2x+1} = 5(3^x) + 2$

$$\begin{aligned} \therefore 3(3^x)^2 - 5(3^x) - 2 &= 0 \\ \therefore 3m^2 - 5m - 2 &= 0 \quad \{m = 3^x\} \\ \therefore (3m+1)(m-2) &= 0 \\ \therefore m &= -\frac{1}{3} \text{ or } 2 \\ \therefore 3^x &= -\frac{1}{3} \text{ or } 3^x = 2 \end{aligned}$$

The first equation is impossible as $3^x > 0$ for all x .

$$\begin{aligned} \therefore 3^x &= 2 \\ \therefore x &= \frac{\ln 2}{\ln 3} \\ (\text{or } x &= \log_3 2) \end{aligned}$$

16 P_n is “ $\sum_{r=1}^n r3^r = \frac{3}{4} [(2n-1)3^n + 1]$ ” for $n \in \mathbb{Z}^+$.

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, LHS = $\sum_{r=1}^1 r3^r = 1(3)^1 = 3$

$$\text{RHS} = \frac{3}{4} [(1)3^1 + 1] = \frac{3}{4} \times 4 = 3 \quad \therefore P_1 \text{ is true.}$$

(2) If P_k is assumed true, then $\sum_{r=1}^k (r3^r) = \frac{3}{4} [(2k-1)3^k + 1]$

$$\begin{aligned} \text{Thus } \sum_{r=1}^{k+1} r3^r &= \sum_{r=1}^k r3^r + (k+1)3^{k+1} \\ &= \frac{3}{4} [(2k-1)3^k + 1] + (k+1)3^{k+1} \quad \{\text{using } P_k\} \\ &= \frac{3}{4} [(2k-1)3^k + 1 + \frac{4}{3}(k+1)3^{k+1}] \\ &= \frac{3}{4} [(2k-1)3^k + 1 + (4k+4)3^k] \\ &= \frac{3}{4} [(6k+3)3^k + 1] \\ &= \frac{3}{4} [(2k+1)3^{k+1} + 1] \\ &= \frac{3}{4} [(2(k+1)-1)3^{k+1} + 1] \end{aligned}$$

Thus P_{k+1} is true whenever P_k is true.

$\therefore$ since P_1 is true, P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

17 Since $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, $b^2x^2 + a^2y^2 = a^2b^2 \dots (*)$

$$\therefore b^2(2x) + a^2(2y) \frac{dy}{dx} = 0$$

$$\therefore \text{ at the point } (x_1, y_1), \frac{dy}{dx} = -\frac{b^2x}{a^2y} = -\frac{b^2x_1}{a^2y_1}$$

$$\therefore \text{ the equation of the tangent is } \frac{y - y_1}{x - x_1} = \frac{-b^2x_1}{a^2y_1}$$

$$\therefore a^2y_1y - a^2y_1^2 = -b^2x_1x + b^2x_1^2$$

$$\therefore a^2y_1y + b^2x_1x = b^2x_1^2 + a^2y_1^2$$

As (x_1, y_1) lies on the curve, $b^2x_1^2 + a^2y_1^2 = a^2b^2$ {from (*)}

$$\therefore \text{ the equation of the tangent is } b^2x_1x + a^2y_1y = a^2b^2$$

$$\text{or } \left(\frac{x_1}{a^2}\right)x + \left(\frac{y_1}{b^2}\right)y = 1 \quad \{\text{dividing throughout by } a^2b^2\}$$

18

Let $P(X, Y)$ be the midpoint of $[AB]$.

$\therefore$ A is at $(2X, 0)$ and B is at $(0, 2Y)$.

Let $[AB]$ have fixed length l units.

$$\therefore (2X)^2 + (2Y)^2 = l^2$$

$$\therefore X^2 + Y^2 = \left(\frac{l}{2}\right)^2$$

which is the equation of a circle, centre $(0, 0)$

and radius $\frac{l}{2}$ units.

19 a

$$\begin{aligned} \frac{Ax + B}{x^2 + 5} + \frac{C}{x - 1} &= \frac{Ax + B}{x^2 + 5} - \frac{C}{1 - x} \\ &= \frac{(Ax + B)(1 - x) - C(x^2 + 5)}{(x^2 + 5)(1 - x)} \\ &= \frac{-(A + C)x^2 + (A - B)x + (B - 5C)}{(x^2 + 5)(1 - x)} \end{aligned}$$

So, if $\frac{x + 5}{(x^2 + 5)(1 - x)} = \frac{Ax + B}{x^2 + 5} + \frac{C}{x - 1}$ for all x then

$$-(A + C) = 0, \quad A - B = 1, \quad \text{and} \quad B - 5C = 5$$

Solving these simultaneously gives $A = 1$, $B = 0$, $C = -1$

b

If $z = \overrightarrow{OP}$ and $w = \overrightarrow{OR}$ then

$\overrightarrow{RP} = z - w$ and $\overrightarrow{OQ} = z + w$ in parallelogram OPQR.

So, if $|z + w| = |z - w|$ the diagonals are equal in length, which is only possible when the parallelogram is a rectangle.

Thus, $\widehat{POR} = \frac{\pi}{2}$, so $\arg w - \arg z = \frac{\pi}{2}$

If P and R were interchanged then $\arg z - \arg w = \frac{\pi}{2}$

Thus, the arguments differ by $\frac{\pi}{2}$.

25 Since $x > y > z > 0$, $\frac{1}{x} < \frac{1}{y} < \frac{1}{z}$

$$\therefore \frac{1}{z} - \frac{1}{y} = \frac{1}{y} - \frac{1}{x} \quad \text{and so} \quad \frac{1}{x} + \frac{1}{z} = \frac{2}{y} \quad \left\{ \frac{1}{x}, \frac{1}{y}, \frac{1}{z} \text{ in arithmetic progression} \right\}$$

$$\therefore \frac{x+z}{xz} = \frac{2}{y}$$

$$\therefore xy + yz = 2xz \quad \dots (*)$$

$$\text{Now } (x - y + z)^2 = x^2 + y^2 + z^2 - 2xy + 2xz - 2yz$$

$$= x^2 - 2xz + z^2 + y^2$$

$$= (x - z)^2 + y^2$$

Hence $x - z$, y , and $x - y + z$ form the sides of a right angled triangle.

26 Each rectangle is determined by choosing the two pairs of opposite sides.

$$\text{This can be done in } \binom{m+2}{2} \times \binom{n+2}{2} = \frac{(m+2)(m+1)(n+2)(n+1)}{4} \text{ ways.}$$

27 The two numbers selected are different and there are $\binom{n}{2}$ different selections.

Of these $(1, 4), (2, 8), (3, 12), \dots, (\frac{n}{4}, n)$ are the different outcomes where one is 4 times the other.

There are $\frac{n}{4}$ of these.

$$\therefore P(\text{one is 4 times the other}) = \frac{\frac{n}{4}}{\binom{n}{2}} = \frac{\frac{n}{4}}{\frac{n(n-1)}{2}} = \frac{1}{2(n-1)}$$

$$\text{From (1) and (2), } 2a^2(1 - \cos 2\theta) = 4a^2 \sin^2 \theta$$

$$\therefore 1 - \cos 2\theta = 2 \sin^2 \theta$$

$$\therefore \sin^2 \theta = \frac{1}{2} - \frac{1}{2} \cos 2\theta$$

e Consider $y = \frac{1}{f(x)}$. When $x = -2$, $y = \frac{1}{f(-2)} = \frac{1}{3}$. $\therefore A(-2, 3) \rightarrow A'(-2, \frac{1}{3})$.

f Consider $y = f^{-1}(x)$. For an inverse function, the point is reflected in the line $y = x$.

$$\therefore A(-2, 3) \rightarrow A'(3, -2).$$

48 a $z = re^{i\theta} = r \operatorname{cis} \theta$

$$\begin{aligned} \therefore z + \frac{1}{z} &= r \operatorname{cis} \theta + \frac{1}{r \operatorname{cis} \theta} \\ &= r \operatorname{cis} \theta + \frac{1}{r} \operatorname{cis}(-\theta) \end{aligned}$$

$$= r(\cos \theta + i \sin \theta) + \frac{1}{r}(\cos \theta - i \sin \theta)$$

$$= \left(r + \frac{1}{r}\right) \cos \theta + i \left(r - \frac{1}{r}\right) \sin \theta$$

Thus $a = \left(r + \frac{1}{r}\right) \cos \theta$ and $b = \left(r - \frac{1}{r}\right) \sin \theta$

b If $z + \frac{1}{z}$ is real then

$$\left(r - \frac{1}{r}\right) \sin \theta = 0$$

$$\therefore r - \frac{1}{r} = 0 \quad \text{or} \quad \sin \theta = 0$$

$$\therefore r^2 = 1 \quad \text{or} \quad \sin \theta = 0$$

$$\therefore r = 1 \quad \text{or} \quad \theta = k\pi, k \in \mathbb{Z} \{r > 0\}$$

$$\therefore r = 1 \quad \text{or} \quad z \text{ is real and non-zero}$$

49 P_n is “If u_n is defined by $u_1 = u_2 = 1$ and $u_{n+2} = u_{n+1} + u_n$ then $u_n \leq 2^n$ ” for $n \in \mathbb{Z}^+$.

Proof: (By the principle of mathematical induction)

(1) If $n = 1$ or 2 , $u_1 = u_2 = 1$ and so $u_1, u_2 \leq 2^1 \quad \therefore P_1$ and P_2 are true.

(2) If P_k is assumed true then $u_k \leq 2^k$

Now $u_{k+1} = u_k + u_{k-1}$, $k \geq 2$

$$\therefore u_{k+1} \leq u_k + u_k \quad \{\text{the sequence } \{u_n\} \text{ is increasing, so } u_{k-1} \leq u_k \text{ for all } k \in \mathbb{Z}\}$$

$$\therefore u_{k+1} \leq 2u_k$$

$$\therefore u_{k+1} \leq 2(2^k) \quad \{\text{by } P_k\}$$

$$\therefore u_{k+1} \leq 2^{k+1}$$

Thus P_{k+1} is true whenever P_k is true, for $k \geq 2$.

$\therefore$ since P_1 and P_2 are true, P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

50 P_n is “ $\left(1 - \frac{1}{2^2}\right) \left(1 - \frac{1}{3^2}\right) \left(1 - \frac{1}{4^2}\right) \dots \left(1 - \frac{1}{n^2}\right) = \frac{n+1}{2n}$ ” for $n \in \mathbb{Z}^+$, $n \geq 2$.

Proof: (By the principle of mathematical induction)

(1) If $n = 2$, LHS = $1 - \frac{1}{2^2} = \frac{3}{4}$ and RHS = $\frac{2+1}{2(2)} = \frac{3}{4} \quad \therefore P_2$ is true.

(2) If P_k is assumed true then

$$\left(1 - \frac{1}{2^2}\right) \left(1 - \frac{1}{3^2}\right) \dots \left(1 - \frac{1}{k^2}\right) = \frac{k+1}{2k}$$

$$\begin{aligned} \therefore \left(1 - \frac{1}{2^2}\right) \left(1 - \frac{1}{3^2}\right) \dots \left(1 - \frac{1}{k^2}\right) \left(1 - \frac{1}{(k+1)^2}\right) &= \frac{k+1}{2k} \left(1 - \frac{1}{(k+1)^2}\right) \\ &= \frac{k+1}{2k} \left(\frac{(k+1)^2 - 1}{(k+1)^2}\right) \\ &= \frac{k+1}{2k} \times \frac{k^2 + 2k}{(k+1)^2} \\ &= \frac{k(k+2)}{2k(k+1)} \\ &= \frac{(k+1)+1}{2(k+1)} \end{aligned}$$

Thus P_{k+1} is true whenever P_k is true.

$\therefore$ since P_2 is true, P_n is true for all $n \geq 2$ {Principle of mathematical induction}

51 a $y = x^3 - 12x^2 + 45x$

$$\begin{aligned}\therefore \frac{dy}{dx} &= 3x^2 - 24x + 45 \\ &= 3(x^2 - 8x + 15) \\ &= 3(x - 3)(x - 5)\end{aligned}$$

which is 0 when $x = 3$ or 5

The sign diagram is:

local maximum at $(3, 54)$

local minimum at $(5, 50)$

b $y = x^3 - 12x^2 + 45x$ meets $y = k$ where $x^3 - 12x^2 + 45x = k$.

Now $y = k$ is a horizontal line, so for 3 real roots we need to observe where $y = k$ meets the curve in 3 places.

Thus $50 < k < 54$ or $k \in]50, 54[$.

52 a Using the cosine rule,

$$\begin{aligned}y^2 &= x^2 + 8^2 - 2(x)(8)\cos\theta \\ \therefore y^2 &= x^2 + 64 - 16x\cos\theta\end{aligned}$$

But $x + y + 8 = 20$

$$\therefore y = 12 - x$$

Hence, $(12 - x)^2 = x^2 + 64 - 16x\cos\theta$

$$\therefore 144 - 24x + x^2 = x^2 + 64 - 16x\cos\theta$$

$$\therefore 16x\cos\theta = 24x - 80$$

$$\therefore \cos\theta = \frac{3x - 10}{2x}$$

b The area, $A = \frac{1}{2}(8x)\sin\theta = 4x\sin\theta$

$$\therefore A^2 = 16x^2\sin^2\theta$$

$$= 16x^2(1 - \cos^2\theta)$$

$$= 16x^2\left(1 - \left(\frac{3x - 10}{2x}\right)^2\right)$$

$$= 16x^2\left(1 - \frac{9x^2 - 60x + 100}{4x^2}\right)$$

$$= 16x^2 - 36x^2 + 240x - 400$$

$$= -20x^2 + 240x - 400$$

$$= -20(x^2 - 12x + 20)$$

c A^2 is a quadratic in x with $a = -20$ and so the shape is

Thus it has a maximum value when $x = \frac{-b}{2a} = \frac{-240}{-40} = 6$

$$\therefore A_{\max}^2 = -20(36 - 72 + 20) = 320$$

So, $A_{\max} = \sqrt{320} = 8\sqrt{5} \text{ cm}^2$ when $x = y = 6$

$\therefore$ the triangle is isosceles.

53 a $u_3 = u_1 + 2d = \frac{1}{k} \dots (1)$

$$u_4 = u_1 + 3d = k$$

$$u_6 = u_1 + 5d = k^2 + 1$$

So, $u_1 + 3d - u_1 - 2d = k - \frac{1}{k}$

$$\therefore d = k - \frac{1}{k} \dots (2)$$

and $u_1 + 5d - u_1 - 3d = k^2 + 1 - k$

$$\therefore 2d = k^2 + 1 - k \dots (3)$$

From (2) and (3), $k^2 - k + 1 = 2k - \frac{2}{k}$

$$\therefore k^3 - 3k^2 + k + 2 = 0$$

$$\therefore (k - 2)(k^2 - k - 1) = 0$$

$$\therefore k = 2 \text{ or } \frac{1 \pm \sqrt{1 - 4(1)(-1)}}{2} = \frac{1 \pm \sqrt{5}}{2}$$

But $k \in \mathbb{Q}$, so $k = 2$

b Using (2), $d = 2 - \frac{1}{2} = \frac{3}{2}$
 $\therefore$ using (1), $u_1 + 2\left(\frac{3}{2}\right) = \frac{1}{2}$
 $\therefore u_1 = -\frac{5}{2}$

Now $u_n = u_1 + (n-1)d$
 $\therefore u_n = -\frac{5}{2} + (n-1)\frac{3}{2}$
 $\therefore u_n = \frac{3}{2}n - 4$
 $\therefore u_n = \frac{3n-8}{2}$ for all $n \in \mathbb{Z}^+$

$$\begin{aligned}\therefore \text{area } \triangle RST &= \frac{1}{2} |\overrightarrow{TR} \times \overrightarrow{TS}| \\ &= \frac{1}{2} \left| \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & -4 & 2 \\ 2 & -1 & 3 \end{vmatrix} \right| \\ &= \frac{1}{2} |-10\mathbf{i} + \mathbf{j} + 7\mathbf{k}| \\ &= \frac{1}{2} \sqrt{100 + 1 + 49} \\ &= \frac{1}{2} \sqrt{150} \\ &= \frac{5}{2} \sqrt{6} \text{ units}^2\end{aligned}$$

55 $x = \log_3 y^2 \quad \therefore y^2 = 3^x = (81^{\frac{1}{4}})^x = 81^{\frac{x}{4}}$
 $\therefore y = (81^{\frac{x}{4}})^{\frac{1}{2}} = 81^{\frac{x}{8}}$

$\therefore 81 = y^{\frac{8}{x}}$ and so $\log_y 81 = \frac{8}{x}$

56

The amplitude $= a = 4$. The period $= 4 = \frac{2\pi}{b} \quad \therefore b = \frac{\pi}{2}$

The basic sine curve has been translated through $\begin{pmatrix} 0 \\ -1 \end{pmatrix}$. $\therefore c = 0, d = -1$

Thus $y = 4 \sin\left(\frac{\pi}{2}x\right) - 1$

Check: $y(3) = 4 \sin\left(\frac{3\pi}{2}\right) - 1 = 4(-1) - 1 = -5 \quad \checkmark$

$y(6) = 4 \sin(3\pi) - 1 = 4(0) - 1 = -1 \quad \checkmark$

57 As A and B are independent, $P(A|B) = P(A)$ and $P(B|A) = P(B)$

$A \cup B'$ is shaded

$$\begin{aligned}\therefore P(A) &= \frac{1}{4} \text{ and } P(B) = \frac{2}{5} \\ \text{and } P(A \cap B) &= P(A)P(B) = \frac{1}{4} \times \frac{2}{5} = \frac{1}{10} \\ \text{So, } P(A \cup B') &= 1 - P(B) + P(A \cap B) \\ &= 1 - \frac{2}{5} + \frac{1}{10} \\ &= \frac{7}{10}\end{aligned}$$

$$\begin{aligned}
 58 \quad \frac{58}{9(3-7i)} &= \frac{58}{9(3-7i)} \left(\frac{3+7i}{3+7i} \right) \\
 &= \frac{58(3+7i)}{9(9+49)} \\
 &= \frac{3+7i}{9}
 \end{aligned}$$

$$\text{Thus, } z^2 = 1 + i + \frac{3+7i}{9} = \frac{12+16i}{9}$$

$$\therefore z = \pm \frac{\sqrt{12+16i}}{3}$$

We now let $\sqrt{12+16i} = c + di$, $c > 0$

$$\therefore 12 + 16i = c^2 - d^2 + 2cdi$$

$$\therefore c^2 - d^2 = 12 \quad \text{and} \quad cd = 8$$

$$\therefore c = 4, d = 2 \quad \text{or} \quad \cancel{c = -4, d = -2} \quad \{\text{as } c > 0\}$$

$$\therefore z = \pm \frac{4+2i}{3}$$

$$\therefore z = \frac{4}{3} + \frac{2}{3}i \quad \text{or} \quad -\frac{4}{3} - \frac{2}{3}i$$

60 For $f(x)$ to be defined we require that

$$-1 \leq 1 + x - x^2 \leq 1$$

$$\therefore x^2 - x - 2 \leq 0 \quad \text{and} \quad x - x^2 \leq 0$$

$$\therefore (x-2)(x+1) \leq 0 \quad \text{and} \quad x(1-x) \leq 0$$

$$\therefore x \in [-1, 0] \cup [1, 2]$$

$$61 \quad \sum_{n=1}^m f(n) = m^3 + 3m$$

$$\therefore f(1) + f(2) + f(3) + \dots + f(m) = m^3 + 3m$$

$$\therefore f(1) + f(2) + f(3) + \dots + f(m-1) = (m-1)^3 + 3(m-1)$$

$$\text{Thus } (m-1)^3 + 3(m-1) + f(m) = m^3 + 3m$$

$$\text{Hence } \cancel{m^3} - 3m^2 + \cancel{3m} - 1 + 3m - 3 + f(m) = \cancel{m^3} + \cancel{3m}$$

$$\therefore f(m) = 3m^2 - 3m + 4$$

$$\text{Hence } f(n) = 3n^2 - 3n + 4 \quad \{\text{replacing } m \text{ by } n\}$$

a $P(X < 85) \approx 0.16$

From the diagram,

$$P(90 < X < 95) \approx 0.34$$

$$63 \quad y = \frac{\tan x}{\sin(2x) + 1} = \frac{\sin x}{\cos x(\sin 2x + 1)} \quad \text{is undefined if } \cos x = 0 \quad \text{or} \quad \sin 2x = -1$$

$$\therefore x = \frac{\pi}{2} + k\pi, \quad k \in \mathbb{Z} \quad \text{or} \quad 2x = -\frac{\pi}{2} + k2\pi, \quad k \in \mathbb{Z}$$

$$\therefore x = -\frac{\pi}{2}, -\frac{\pi}{4}, \frac{\pi}{2}, \frac{3\pi}{4} \quad \text{for } x \in [-\pi, \pi]$$

$$\therefore \text{the vertical asymptotes are: } x = -\frac{\pi}{2}, x = -\frac{\pi}{4}, x = \frac{\pi}{2}, x = \frac{3\pi}{4}.$$

There are no horizontal asymptotes.

$$\mathbf{b} \quad |\mathbf{a} \times \mathbf{b}| = \sqrt{25 + 4 + 1} = \sqrt{30} \text{ units}$$

$\therefore \frac{1}{\sqrt{30}}(5\mathbf{i} - 2\mathbf{j} + \mathbf{k})$ is a unit vector perpendicular to both $\mathbf{a}$ and $\mathbf{b}$.

$\therefore$ the required vector is $\frac{5}{\sqrt{30}}(5\mathbf{i} - 2\mathbf{j} + \mathbf{k}) = \frac{\sqrt{30}}{6}(5\mathbf{i} - 2\mathbf{j} + \mathbf{k})$

65 $z = \cos \theta + i \sin \theta = \text{cis } \theta$ has modulus 1 and argument θ .

$$z^2 = (\text{cis } \theta)^2 = \text{cis } 2\theta \quad \{\text{De Moivre}\}$$

$\therefore z^2$ has modulus 1 and argument 2θ

$1 - z^2$ is found using vector subtraction on the diagram.

$\triangle OAB$ is isosceles as $OA = BA = 1$

Hence $\alpha_1 = \alpha_2$ {isosceles $\triangle$ theorem}

As z^2 and $-z^2$ are parallel,

$$\widehat{OAB} = 2\theta \quad \{\text{equal alternate angles}\}$$

$$\text{Thus } 2\alpha + 2\theta = \pi \text{ and so } \alpha = \frac{\pi}{2} - \theta$$

$$\text{Now } \arg(1 - z^2) = -\alpha_1 = \theta - \frac{\pi}{2}$$

The angle at the centre of a circle is twice the angle on the circle subtended by the same arc.

96 P_n is “ $x^n - y^n$ has factor $x - y$ ” for $n \in \mathbb{Z}^+$.

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, $x^1 - y^1$ has factor $x - y$ ✓ $\therefore P_1$ is true.

(2) If P_k is assumed true then $x^k - y^k = (x - y)f_k(x, y)$, where $f_k(x, y)$ is another factor.

$$\begin{aligned} \text{Now } x^{k+1} - y^{k+1} &= x(x^k - y^k) + xy^k - y^{k+1} \\ &= x(x - y)f_k(x, y) + y^k(x - y) \\ &= (x - y)[xf_k(x, y) + y^k] \\ &\equiv (x - y)f_{k+1}(x, y) \end{aligned}$$

$\therefore x^{k+1} - y^{k+1}$ has factor $x - y$.

Thus P_{k+1} is true whenever P_k is true.

$\therefore$ since P_1 is true, P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

We complete the rhombus OACB (each side has length 1).

Using the cosine rule in triangle OAC,

$$\begin{aligned} |\mathbf{u} - \mathbf{v}|^2 &= 1^2 + 1^2 - 2(1)(1)\cos\theta \\ \therefore |\mathbf{u} - \mathbf{v}|^2 &= 2 - 2\cos\theta \\ \therefore |\mathbf{u} - \mathbf{v}| &= \sqrt{2 - 2\cos\theta} \end{aligned}$$

Now in $\triangle OAB$, $\widehat{OAB} = 180^\circ - \theta$, and using the cosine rule again,

$$\begin{aligned} |\mathbf{u} + \mathbf{v}|^2 &= 1^2 + 1^2 - 2(1)(1)\cos(180^\circ - \theta) \\ &= 2 - 2(-\cos\theta) \\ &= 2 + 2\cos\theta \\ \therefore |\mathbf{u} + \mathbf{v}| &= \sqrt{2 + 2\cos\theta} \end{aligned}$$

b Now, if $|\mathbf{u} + \mathbf{v}| = 5|\mathbf{u} - \mathbf{v}|$ then

$$\begin{aligned} \sqrt{2 + 2\cos\theta} &= 5\sqrt{2 - 2\cos\theta} \\ \therefore 2 + 2\cos\theta &= 25(2 - 2\cos\theta) \\ \therefore 2 + 2\cos\theta &= 50 - 50\cos\theta \\ \therefore 52\cos\theta &= 48 \\ \therefore \cos\theta &= \frac{12}{13} \end{aligned}$$

$$= (C^4 - 6C^2S^2 + S^4) + i(4C^3S - 4CS^3)$$

Equating real and imaginary parts, $\sin 4\theta = 4C^3S - 4CS^3$ and $\cos 4\theta = C^4 - 6C^2S^2 + S^4$.

$$\text{Hence, } \tan 4\theta = \frac{\sin 4\theta}{\cos 4\theta} = \frac{4C^3S - 4CS^3}{C^4 - 6C^2S^2 + S^4}$$

b $x^4 + 4x^3 - 6x^2 - 4x + 1 = 0$

If we let $x = \tan \theta$ then $\tan^4 \theta + 4 \tan^3 \theta - 6 \tan^2 \theta - 4 \tan \theta + 1 = 0$

$$\therefore 1 - 6 \tan^2 \theta + \tan^4 \theta = 4 \tan \theta - 4 \tan^3 \theta$$

$$\therefore \frac{4 \tan \theta - 4 \tan^3 \theta}{1 - 6 \tan^2 \theta + \tan^4 \theta} = 1$$

118 a The system has augmented matrix

$$\begin{pmatrix} 2 & -1 & 3 & 4 \\ 2 & 1 & a+3 & 10-a \\ 4 & 6 & a^2+6 & a^2 \end{pmatrix} = \begin{pmatrix} 2 & -1 & 3 & 4 \\ 0 & 2 & a & 6-a \\ 0 & 8 & a^2 & a^2-8 \end{pmatrix} \begin{array}{l} R_2 \rightarrow R_2 - R_1 \\ R_3 \rightarrow R_3 - 2R_1 \end{array}$$

$$= \begin{pmatrix} 2 & -1 & 3 & 4 \\ 0 & 2 & a & 6-a \\ 0 & 0 & a^2-4a & a^2+4a-32 \end{pmatrix} \quad R_3 \rightarrow R_3 - 4R_2$$

b The last equation is $a(a-4)z = (a+8)(a-4)$

i The system has no solutions if the LHS = 0 and the RHS $\neq 0$.

This occurs when $a = 0$, since we get $0z = -32$.

The line of intersection of any two planes is parallel to the third.

ii The system has infinitely many solutions if the last equation has the form $0z = 0$, which is true for any real number z . This occurs when $a = 4$.

$$\text{The augmented matrix becomes } \begin{pmatrix} 2 & -1 & 3 & 4 \\ 0 & 2 & 4 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$\begin{aligned}
 &\text{Letting } z = t, \quad 2y + 4t = 2 \\
 &\quad \therefore y + 2t = 1 \\
 &\quad \therefore y = 1 - 2t \\
 &\text{and so } 2x - (1 - 2t) + 3t = 4 \\
 &\quad \therefore 2x - 1 + 2t + 3t = 4 \\
 &\quad \therefore x = \frac{5 - 5t}{2}
 \end{aligned}$$

$\therefore$ when $a = 4$, there are infinitely many solutions of the form

$$x = \frac{5 - 5t}{2}, \quad y = 1 - 2t, \quad z = t, \quad t \in \mathbb{R}.$$

The planes meet in a common line of intersection.

iii The system has a unique solution for all other values of a . So, $a \neq 0$ or 4 .

$$\text{In this case } z = \frac{a + 8}{a}$$

$$\begin{aligned}
 \therefore 2y + a \left(\frac{a + 8}{a} \right) &= 6 - a & \text{and } 2x + a + 1 + 3 \left(\frac{a + 8}{a} \right) &= 4 \\
 \therefore 2y &= 6 - a - a - 8 & \therefore 2x &= 4 - a - 1 - 3 - \frac{24}{a} \\
 &= -2a - 2 & &= -a - \frac{24}{a} \\
 \therefore y &= -a - 1 & \therefore x &= -\frac{a}{2} - \frac{12}{a}
 \end{aligned}$$

$\therefore$ when $a \neq 0$ or 4 , there is a unique solution of the form

$$x = -\frac{a}{2} - \frac{12}{a}, \quad y = -a - 1, \quad z = \frac{a + 8}{a}$$

When $a = 2$, the solution is $x = -7$, $y = -3$, $z = 5$.

This means that the 3 planes meet at one point only.

119 $f(x) = xe^{1-2x^2}$

 &= e^{1-2x^2}(-4x + 16x^3 - 8x) \\
 &= e^{1-2x^2}(16x^3 - 12x)
 \end{aligned}$$

c $f''(x) = 0$ when $16x^3 - 12x = 0$
 $\therefore 4x(4x^2 - 3) = 0$
 $\therefore x = 0$ or $\pm \frac{\sqrt{3}}{2}$

b $f'(x) = e^{1-2x^2}(1 + 2x)(1 - 2x)$

$\therefore$ there is a local minimum at $(-\frac{1}{2}, -\frac{\sqrt{e}}{2})$
 and a local maximum at $(\frac{1}{2}, \frac{\sqrt{e}}{2})$.

d As $x \rightarrow \infty$, $f(x) \rightarrow 0$ (above).
 As $x \rightarrow -\infty$, $f(x) \rightarrow 0$ (below).

f If $\int_0^k xe^{1-2x^2} dx = \frac{e-1}{4}$
 then $\frac{1}{-4} \int_0^k e^{1-2x^2}(-4x) dx = \frac{e-1}{4}$
 $\therefore [e^{1-2x^2}]_0^k = 1 - e$
 $\therefore e^{1-2k^2} - e = 1 - e$
 $\therefore e^{1-2k^2} = 1$
 $\therefore 1 - 2k^2 = 0$
 $\therefore k = \pm \frac{1}{\sqrt{2}}$
 But $k > 0$, so $k = \frac{1}{\sqrt{2}}$

121 If $u = \ln x$, $\frac{du}{dx} = \frac{1}{x}$ and $\therefore \int \sin(\ln x) \, dx = \int \sin u(x \, du)$

$$= \int \sin u e^u \, du$$

$$= \int e^u \sin u \, du \dots (*)$$

Now consider $\int e^x \sin x \, dx$ using integration by parts

$$\begin{aligned} \therefore \int e^x \sin x \, dx &= e^x \sin x - \int e^x \cos x \, dx \\ &= e^x \sin x - [e^x \cos x - \int e^x (-\sin x) \, dx] \end{aligned}$$

Thus $\int e^x \sin x \, dx = e^x (\sin x - \cos x) - \int e^x \sin x \, dx$

$$\therefore 2 \int e^x \sin x \, dx = e^x (\sin x - \cos x)$$

$$\therefore \int e^x \sin x \, dx = \frac{e^x}{2} (\sin x - \cos x)$$

Hence, in (*), $\int \sin(\ln x) \, dx = \frac{e^u}{2} (\sin u - \cos u)$

$$= \frac{x}{2} (\sin(\ln x) - \cos(\ln x))$$

122 a Since $P(x)$ is a real polynomial, both $1 + ki$ and $1 - ki$ are zeros, $k \in \mathbb{Z}$.
These have sum 2 and product $1 + k^2$ and therefore come from the quadratic factor $x^2 - 2x + 1 + k^2$.

b By comparison with $P(x)$, $1 + k^2$ is a factor of -10 .
 $\therefore 1 + k^2 = \pm 1, \pm 2, \pm 5, \pm 10$ where $k \in \mathbb{Z}$
 $\therefore k^2 = 0, 1, 4, 9$
 $\therefore k = 0, \pm 1, \pm 2, \pm 3$

c As p and q are integer zeros, they come from
 $(x - p)(x - q) = x^2 - (p + q)x + pq$
 $\therefore pq$ is a factor of -10
The possibilities are as shown in the table:

$1 + k^2$	pq
1	-10
2	-5
5	-2
10	-1

d Without loss of generality we assume $p > q$. Then as $p + q = -1$, the only possibility is $p = 1$, $q = -2$, and $1 + k^2 = 5 \therefore k = \pm 2$
 $\therefore P(x) = (x - 1)(x + 2)(x - 1 - 2i)(x - 1 + 2i)$
So, the zeros of $P(x)$ are 1, -2 , $1 + 2i$, and $1 - 2i$.

123 a $f'(x)$ near a has sign diagram

$f'(x)$ near b has sign diagram , but $f'(b) \neq 0$

$f'(x)$ near c has sign diagram , but $f'(c) = 0$

$\therefore$ there is a local minimum at $x = a$, a non-stationary inflection at $x = b$, and a stationary inflection at $x = c$.

b $f(x) = f_1(x) + k$, k a constant

124 a

$$\sin 30^\circ = \frac{r_1}{10 - r_1} \quad \{\text{in } \triangle OAB\}$$

$$\therefore \frac{1}{2} = \frac{r_1}{10 - r_1} \quad \therefore r_1 = \frac{10}{3}$$

$$\text{In } \triangle DBN, \sin 30^\circ = \frac{r_1 - r_2}{r_1 + r_2} = \frac{1}{2}$$

$$\therefore 2r_1 - 2r_2 = r_1 + r_2$$

$$\therefore r_1 = 3r_2$$

$$\therefore r_2 = \frac{1}{3}r_1$$

So, in successive circles, radii are reduced by a factor of 3.

$$\therefore r_2 = \frac{10}{9}, \quad r_3 = \frac{10}{27}, \quad r_4 = \frac{10}{81}, \quad \text{and so on.}$$

Thus the total area of the circles = $\pi r_1^2 + \pi r_2^2 + \pi r_3^2 + \pi r_4^2 + \dots$

$$= \pi \left[\left(\frac{10}{3}\right)^2 + \left(\frac{10}{9}\right)^2 + \left(\frac{10}{27}\right)^2 + \left(\frac{10}{81}\right)^2 + \dots \right]$$

$$= \pi \times \left(\frac{10}{3}\right)^2 \left[1 + \left(\frac{1}{3}\right)^2 + \left(\frac{1}{3}\right)^4 + \left(\frac{1}{3}\right)^6 + \dots \right]$$

$$= \pi \times \frac{100}{9} \times \left(\frac{1}{1 - \frac{1}{9}} \right)$$

$$= \frac{25\pi}{2} \text{ units}^2$$

b We let $\frac{\alpha}{2}$ replace 30° in the calculations of **a**, and let $a = \sin\left(\frac{\alpha}{2}\right)$.

In this case $a = \frac{r_1}{10 - r_1}$, and so $r_1 = \frac{10a}{1 + a}$

Now $a = \frac{r_1 - r_2}{r_1 + r_2}$ {using $\triangle DBN$ }

$$\therefore a(r_1 + r_2) = r_1 - r_2$$

$$\therefore r_2(a + 1) = r_1(1 - a)$$

$$\therefore r_2 = r_1 \left(\frac{1 - a}{a + 1} \right) = \frac{10a}{1 + a} \left(\frac{1 - a}{a + 1} \right) = \frac{10a(1 - a)}{(a + 1)^2}$$

Thus $r_3 = r_2 \left(\frac{1 - a}{a + 1} \right) = \frac{10a(1 - a)^2}{(a + 1)^3}$, and so on.

$$\therefore \text{total area} = \pi(r_1^2 + r_2^2 + r_3^2 + r_4^2 + \dots)$$

$$= \pi \left[\left(\frac{10a}{1 + a} \right)^2 + \left(\frac{10a(1 - a)}{(1 + a)^2} \right)^2 + \left(\frac{10a(1 - a)^2}{(1 + a)^3} \right)^2 + \dots \right]$$

$$= \pi \frac{100a^2}{(1 + a)^2} \left[1 + \left(\frac{1 - a}{1 + a} \right)^2 + \left(\frac{1 - a}{1 + a} \right)^4 + \dots \right]$$

This is the sum of an infinite geometric series which converges since $\left| \frac{1 - \sin\left(\frac{\alpha}{2}\right)}{1 + \sin\left(\frac{\alpha}{2}\right)} \right| < 1$.

$$\therefore \text{total area} = \pi \times \frac{100a^2}{(1 + a)^2} \times \frac{1}{1 - \left(\frac{1 - a}{1 + a} \right)^2}$$

$$= \pi \times \frac{100a^2}{(1 + a)^2 - (1 - a)^2}$$

$$= \pi \times \frac{100a^2}{4a}$$

$$= 25\pi a$$

$$\therefore a^2 + 6b^2 = 14 \text{ and } ab = -2$$

$$\therefore a^2 + 6\left(\frac{-2}{a}\right)^2 = 14$$

$$\therefore a^2 + \frac{24}{a^2} - 14 = 0$$

$$\therefore 3a^2 + 2\left(\frac{-2}{a}\right)^2 - 14 = 0$$

$$\therefore 3a^2 + \frac{8}{a^2} - 14 = 0$$

$$\therefore 3a^4 - 14a^2 + 8 = 0$$

$$\text{Now } \tan \theta = \frac{PN}{b} \text{ and } \tan \phi = \frac{PM}{a}$$

$$\therefore PN = b \tan \theta \text{ and } PM = a \tan \phi$$

But MN is constant, so we let

$$b \tan \theta + a \tan \phi = k$$

Differentiating with respect to θ gives

$$b \sec^2 \theta + a \sec^2 \phi \frac{d\phi}{d\theta} = 0$$

$$\therefore \frac{d\phi}{d\theta} = \frac{-b \sec^2 \theta}{a \sec^2 \phi} = \frac{-b \cos^2 \phi}{a \cos^2 \theta}$$

b Now $\text{speed} = \frac{\text{distance}}{\text{time}} \quad \therefore \text{time} = \frac{\text{distance}}{\text{speed}}$

$\therefore$ the total time T to travel from R to P to Q is given by

$$\begin{aligned} T &= \frac{PR}{v_1} + \frac{PQ}{v_2} \\ &= \frac{b}{v_1 \cos \theta} + \frac{a}{v_2 \cos \phi} \quad \left\{ \text{since } \cos \theta = \frac{b}{PR}, \cos \phi = \frac{a}{PQ} \right\} \\ &= \frac{b}{v_1} [\cos \theta]^{-1} + \frac{a}{v_2} [\cos \phi]^{-1} \\ \therefore \frac{dT}{d\theta} &= -\frac{b}{v_1} [\cos \theta]^{-2} \times -\sin \theta - \frac{a}{v_2} [\cos \phi]^{-2} \times -\sin \phi \frac{d\phi}{d\theta} \\ &= \frac{b \sin \theta}{v_1 \cos^2 \theta} + \frac{a \sin \phi}{v_2 \cos^2 \phi} \left(\frac{-b \cos^2 \phi}{a \cos^2 \theta} \right) \quad \{\text{from a}\} \\ &= \frac{b \sin \theta}{v_1 \cos^2 \theta} - \frac{b \sin \phi}{v_2 \cos^2 \theta} \\ &= \frac{b}{\cos^2 \theta} \left[\frac{\sin \theta}{v_1} - \frac{\sin \phi}{v_2} \right] \\ \therefore \frac{dT}{d\theta} &= 0 \quad \text{when} \quad \frac{\sin \theta}{v_1} = \frac{\sin \phi}{v_2}, \quad \text{or when} \quad \frac{\sin \theta}{\sin \phi} = \frac{v_1}{v_2}. \end{aligned}$$

So, there is only one case when $\frac{dT}{d\theta} = 0$.

The question is whether we have a minimum or a maximum T in this case.

We construct the following sign diagram for $\frac{dT}{d\theta}$:

$\therefore$ the minimum value of T occurs when $\frac{dT}{d\theta} = 0$.

133 Let X be the outcome of a spin.
Since spins are independent,

$$\begin{aligned} &P(\text{player spins } x_1 \text{ and operator spins } x_2) \\ &= P(x_1) \times P(x_2) \end{aligned}$$

For example, $P(\text{player spins 2 and operator spins 4}) = \frac{3}{8} \times \frac{1}{8} = \frac{3}{64}$

	2	$\frac{3}{16}$	$\frac{9}{64}$	$\frac{3}{64}$
	4	$\frac{1}{16}$	$\frac{3}{64}$	$\frac{1}{64}$

In these 3 the player wins $\therefore$ gaining $a - k$ dollars

In these 6 the player loses $\therefore$ gaining $-k$ dollars

So, $x = -3$ and $x \approx -7.64$ are the solutions.

- 2 Let n be the number of years after winter 1969 and let u_n be the number of trees at time n . Each summer, 10% die out and 100 new ones are planted, so $u_{n+1} = 0.9u_n + 100$. We also know that $u_{11} = 1200$, since there were 1200 trees in 1980. We hence have a sequence of the form $u_{n+1} = au_n + b$, $n = 1, 2, 3, 4, 5, \dots$

$$\text{Now } u_2 = au_1 + b$$

$$u_3 = au_2 + b = a(au_1 + b) + b = a^2u_1 + ab + b$$

$$u_4 = au_3 + b = a(a^2u_1 + ab + b) + b = a^3u_1 + a^2b + ab + b \quad \text{and so on}$$

This suggests: $u_{n+1} = a^n u_1 + b(1 + a + a^2 + \dots + a^{n-1})$

$$\therefore u_{n+1} = a^n u_1 + b \left(\frac{1 - a^n}{1 - a} \right) \quad \{\text{sum of a geometric series}\}$$

- a In this case $a = 0.9$ and $b = 100$

$$\therefore u_{n+1} = (0.9)^n u_1 + 100 \left(\frac{1 - (0.9)^n}{1 - 0.9} \right)$$

$$\therefore u_{n+1} = (0.9)^n u_1 + 1000(1 - (0.9)^n)$$

$$\text{But } u_{11} = (0.9)^{10} u_1 + 1000(1 - (0.9)^{10}) = 1200$$

$$\therefore 0.34868u_1 + 651.32 \approx 1200$$

$$\therefore u_1 \approx \frac{548.68}{0.34868} \approx 1574 \text{ trees}$$

$\therefore$ there were about 1574 trees at the end of winter in 1970.

- b As n gets large,

$$(0.9)^n \rightarrow 0$$

$$\text{and } 1 - (0.9)^n \rightarrow 1$$

$$\therefore u_{n+1} \rightarrow 1000$$

This indicates a stable number of trees at 1000.

- 3 Let $P(A \text{ hits}) = 2p$ and $P(B \text{ hits}) = p$

$$\text{Now } P(\text{at least one hits}) = \frac{1}{2}, \quad \text{so } P(\text{both miss}) = \frac{1}{2}$$

$$\therefore (1 - 2p)(1 - p) = \frac{1}{2}$$

$$\therefore 4p^2 - 6p + 1 = 0$$

$$\therefore p = \frac{3 \pm \sqrt{5}}{4}$$

$$\therefore p = \frac{3 - \sqrt{5}}{4} \quad \left\{ \text{since } \frac{3 + \sqrt{5}}{4} > 1 \right\}$$

$$\therefore 2p = \frac{3 - \sqrt{5}}{2} \approx 0.382$$

$$\therefore P(A \text{ hits}) \approx 0.382$$

- 4 P_n is “ $\frac{1}{a(a+1)} + \frac{1}{(a+1)(a+2)} + \frac{1}{(a+2)(a+3)} + \dots + \frac{1}{(a+n-1)(a+n)} = \frac{n}{a(a+n)}$ ”
for $n \in \mathbb{Z}^+$.

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, $\text{LHS} = \frac{1}{a(a+1)}$ and $\text{RHS} = \frac{1}{a(a+1)} \therefore P_1$ is true.

(2) If P_k is assumed true then

$$\frac{1}{a(a+1)} + \frac{1}{(a+1)(a+2)} + \dots + \frac{1}{(a+k-1)(a+k)} = \frac{k}{a(a+k)}$$

$$\begin{aligned} \text{Thus } & \frac{1}{a(a+1)} + \frac{1}{(a+1)(a+2)} + \dots + \frac{1}{(a+k-1)(a+k)} + \frac{1}{(a+k)(a+k+1)} \\ &= \frac{k}{a(a+k)} + \frac{1}{(a+k)(a+k+1)} \quad \{\text{using } P_k\} \\ &= \frac{k}{a(a+k)} \left(\frac{a+k+1}{a+k+1} \right) + \frac{1}{(a+k)(a+k+1)} \left(\frac{a}{a} \right) \\ &= \frac{ak + k^2 + k + a}{a(a+k)(a+k+1)} \\ &= \frac{(a+k)(k+1)}{a(a+k)(a+k+1)} \\ &= \frac{k+1}{a(a+k+1)} \end{aligned}$$

Thus P_{k+1} is true whenever P_k is true.

$\therefore$ since P_1 is true, P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

- 5 Now $2z + w = i$,

so $6z + 3w = 3i$

Also, $z - 3w = 7 - 10i$

$$\therefore 7z = 7 - 7i$$

$$\therefore z = 1 - i$$

$$\begin{aligned} \therefore w &= i - 2z \\ &= i - 2 + 2i \\ &= -2 + 3i \end{aligned}$$

Thus $z + w = -1 + 2i$

- 6 **Proof:** (By contradiction)

Suppose neither equation has real roots

$$\therefore b_1^2 - 4c_1 < 0 \text{ and } b_2^2 - 4c_2 < 0$$

$$\therefore b_1^2 + b_2^2 < 4c_1 + 4c_2$$

$$\therefore b_1^2 + b_2^2 < 4(c_1 + c_2)$$

$$\therefore b_1^2 + b_2^2 < 2b_1b_2 \quad \{\text{given } b_1b_2 = 2(c_1 + c_2)\}$$

$$\therefore b_1^2 - 2b_1b_2 + b_2^2 < 0$$

$$\therefore (b_1 - b_2)^2 < 0$$

which is a contradiction as no perfect square of real numbers can be negative.

Thus the supposition is false and so at least one of the equations has real roots.

$$\therefore \alpha = \arctan \left(\frac{\tan 10^\circ \times \tan 30^\circ}{\tan 40^\circ} \right)$$

9 Consider a model of the mountain. We cut the model along $[CT]$ and flatten it out. To make AB as short as possible, $[AB]$ is a straight line on a sector of a circle.

The circumference of the cone's base is equal to the arc length of the sector, so

$$2\pi \times 2 = \theta \times 3$$

$$\therefore \theta = \frac{4\pi}{3}$$

$$\text{Thus } \widehat{ATB} = \frac{1}{2}\theta = \frac{2\pi}{3}$$

$$\text{and } AB^2 = 3^2 + \left(\frac{3}{2}\right)^2 - 2 \times 3 \times \frac{3}{2} \cos\left(\frac{2\pi}{3}\right) \quad \{\text{cosine rule}\}$$

$$\therefore AB = \sqrt{3^2 + (1.5)^2 - 9 \cos\left(\frac{2\pi}{3}\right)}$$

$$\therefore AB \approx 3.97 \text{ km}$$

$$\begin{aligned}\mathbf{10} \quad \log_3(x - k) + \log_3(x + 2) &= 1 \\ \therefore \log_3(x - k)(x + 2) &= 1 \\ \therefore (x - k)(x + 2) &= 3^1 = 3 \\ \therefore x^2 + [2 - k]x - 2k - 3 &= 0\end{aligned}$$

$$\begin{aligned}\text{This quadratic in } x \text{ has } \Delta &= (2 - k)^2 - 4(1)(-2k - 3) \\ &= 4 - 4k + k^2 + 8k + 12 \\ &= k^2 + 4k + 16 \\ &= (k + 2)^2 + 12\end{aligned}$$

Since $(k + 2)^2 \geq 0$, $\Delta \geq 0$ for all k $\therefore$ the original equation has a real solution for all real k .

$$\begin{aligned}\mathbf{11} \quad \mathbf{a} \quad u_1 &= \frac{1}{\sin \theta} - \sin \theta = \frac{1 - \sin^2 \theta}{\sin \theta} = \frac{\cos^2 \theta}{\sin \theta} \\ u_4 &= \frac{1}{\cos \theta} - \cos \theta = \frac{1 - \cos^2 \theta}{\cos \theta} = \frac{\sin^2 \theta}{\cos \theta} \\ \therefore \frac{u_2}{u_1} &= \frac{\cos \theta}{\left(\frac{\cos^2 \theta}{\sin \theta}\right)} = \tan \theta, \quad \frac{u_3}{u_2} = \frac{\sin \theta}{\cos \theta} = \tan \theta, \quad \text{and} \quad \frac{u_4}{u_3} = \frac{\left(\frac{\sin^2 \theta}{\cos \theta}\right)}{\sin \theta} = \tan \theta\end{aligned}$$

So, the sequence is geometric with $u_1 = \frac{\cos^2 \theta}{\sin \theta}$ and $r = \tan \theta$

$$\therefore u_n = u_1 r^{n-1} = \frac{\cos^2 \theta}{\sin \theta} \times (\tan \theta)^{n-1} = \frac{\cos \theta}{\tan \theta} \times \tan^{n-1} \theta$$

b $u_1 = 1, u_2 = \cos^1 \theta, u_3 = \cos^3 \theta, u_4 = \cos^7 \theta, u_5 = \cos^{15} \theta$

We notice that $u_5 = u_4^2 \cos \theta, u_4 = u_3^2 \cos \theta, u_3 = u_2^2 \cos \theta, u_2 = u_1^2 \cos \theta$, suggesting that $u_1 = 1$ and $u_{n+1} = u_n^2 \cos \theta$ for all $n \in \mathbb{Z}^+$.

b We need to solve $2p^2 - p^4 > \frac{1}{2}$
 We graph $y = 2x^2 - x^4$ in $[0, 1]$.

23 $h(x) = x^3 - 6tx^2 + 11t^2x - 6t^3$

a $h(t) = t^3 - 6t^3 + 11t^3 - 6t^3 = 0$
 $\therefore x = t$ is a zero of $h(x)$.

b By inspection, $h(x) = (x - t)(x^2 - 5tx + 6t^2)$
 $\therefore h(x) = (x - t)(x - 2t)(x - 3t)$

c $y = x^3 + 6x^2$ meets $y = -6 - 11x$ where $x^3 + 6x^2 = -6 - 11x$
 $\therefore x^3 + 6x^2 + 11x + 6 = 0$ which is $h(x)$ when $t = -1$
 $\therefore (x + 1)(x + 2)(x + 3) = 0$ {using **b**}
 $\therefore x = -1, -2, \text{ or } -3$

So, the graphs meet at $(-1, 5)$, $(-2, 16)$, and $(-3, 27)$.

24 $\sum_{i=1}^{25} x_i = 1650$ and $\sum_{i=1}^{25} x_i^2 = 115\,492$

Now $s_n^2 = \frac{\sum_{i=1}^{25} (x_i - \bar{x})^2}{25} = \frac{6592}{25} \approx 264$

$\therefore$ the variance ≈ 264

$$\therefore x^2 \approx 41.0127$$

a As a , b , and c are real, all the coefficients of $P(z)$ are real.

Consequently $-3 + 2i$ and $-3 - 2i$ are both zeros.

They have sum -6 and product $9 + 4 = 13$.

$\therefore z^2 + 6z + 13$ is a factor of $P(z)$.

Thus $P(z) = (z + 2)(z^2 + 6z + 13)$

$$= z^3 + 8z^2 + 25z + 26$$

$\therefore a = 8$, $b = 25$, and $c = 26$

b If $P(z) \geq 0$ then $(z + 2)(z^2 + 6z + 13) \geq 0$.

Now $z^2 + 6z + 13 > 0$ for all z , since its roots are complex and it has shape 

$\therefore P(z) \geq 0$ provided $z + 2 \geq 0$

$$\therefore z \geq -2$$

69 P_n is “ $3(5^{2n+1}) + 2^{3n+1}$ is divisible by 17” for $n \in \mathbb{Z}^+$.

Proof: (By the principle of mathematical induction)

(1) If $n = 1$, $3(5^3) + 2^{3+1} = 391 = 17 \times 23$ where $23 \in \mathbb{Z}$ $\therefore P_1$ is true.

(2) If P_k is assumed true, then $3(5^{2k+1}) + 2^{3k+1} = 17A$ for some $A \in \mathbb{Z}$

$$\begin{aligned} \text{Thus } &3(5^{2(k+1)+1}) + 2^{3(k+1)+1} \\ &= 3(5^{2k+1+2}) + 2^{3k+1+3} \\ &= 3 \times 25 \times 5^{2k+1} + 8 \times 2^{3k+1} \\ &= 25(17A - 2^{3k+1}) + 8 \times 2^{3k+1} \quad \{\text{by rearranging and substituting } P_k\} \\ &= 25 \times 17 \times A + (8 - 25)2^{3k+1} \\ &= 25 \times 17 \times A - 17 \times 2^{3k+1} \\ &= 17(25A - 2^{3k+1}) \quad \text{where } 25A - 2^{3k+1} \in \mathbb{Z} \end{aligned}$$

Thus P_{k+1} is true whenever P_k is true.

$\therefore$ since P_1 is true, P_n is true for all $n \in \mathbb{Z}^+$ {Principle of mathematical induction}

70 a If $x = a^{\frac{1}{3}} + b^{\frac{1}{3}}$ then $x^3 = (a^{\frac{1}{3}} + b^{\frac{1}{3}})^3$

$$\therefore x^3 = (a^{\frac{1}{3}})^3 + 3(a^{\frac{1}{3}})^2 b^{\frac{1}{3}} + 3(a^{\frac{1}{3}})(b^{\frac{1}{3}})^2 + (b^{\frac{1}{3}})^3$$

$$\therefore x^3 = a + b + 3a^{\frac{1}{3}}b^{\frac{1}{3}}(a^{\frac{1}{3}} + b^{\frac{1}{3}})$$

$$\therefore x^3 = 3(ab)^{\frac{1}{3}}x + (a + b)$$

b $x^3 = 6x + 6$ is of the above form where $(ab)^{\frac{1}{3}} = 2$ and $a + b = 6$

$$\therefore ab = 8 \quad \text{and} \quad a + b = 6$$

$$\therefore a = 2, b = 4 \quad \text{or} \quad a = 4, b = 2$$

Thus $x = 4^{\frac{1}{3}} + 2^{\frac{1}{3}}$ is a root of $x^3 = 6x + 6$

The graph of $f(x) = x^3 - 6x - 6$ is:

As a cubic has at most two turning points, it is clear that $x = \sqrt[3]{4} + \sqrt[3]{2}$ is the only real zero of $f(x) = x^3 - 6x - 6$, and hence is the only real solution of $x^3 = 6x + 6$.

71 $y = 3 \frac{dy}{dx}$

$$\therefore \frac{dy}{dx} = \frac{y}{3}$$

$$\therefore \frac{dx}{dy} = \frac{3}{y} \quad \left\{ \frac{dy}{dx} \times \frac{dx}{dy} = 1 \right\}$$

$$\therefore x = \int \frac{3}{y} dy$$

$$\therefore x = 3 \ln |y| + c$$

$$\therefore x = 3 \ln y + c \quad \{\text{as } y > 0, \text{ given}\}$$

Now when $x = 0$, $y = 3$

$$\therefore 0 = 3 \ln 3 + c$$

$$\therefore c = -3 \ln 3$$

Hence, $x = 3 \ln y - 3 \ln 3$

$$\therefore \frac{x}{3} = \ln y - \ln 3 = \ln \left(\frac{y}{3} \right)$$

$$\therefore \frac{y}{3} = e^{\frac{x}{3}}$$

$$\therefore y = 3e^{\frac{x}{3}}$$

72 a Let u_{n+1} be the amount still owing after n quarters and let R be the repayment each quarter. Each quarter, interest is charged at $\frac{12\%}{4} = 3\%$, so $u_{n+1} = 1.03u_n - R$.

$$\text{From 2, } u_{n+1} = (1.03)^n u_1 - R \left(\frac{1 - (1.03)^n}{1 - 1.03} \right)$$

We want $u_{n+1} = 0$, $u_1 = 20\,000$, and $n = 40$

$$\text{Thus } (1.03)^{40} \times 20\,000 + \frac{100R}{3} (1 - (1.03)^{40}) = 0$$

$$\therefore 65\,240.756 \approx R \times 75.401\,26$$

$$\therefore R \approx 865.25$$

So, repayments of \$865.25 each quarter are required.

- 73 a** We select the captain first and then the other 10 from the remaining 21.

This can be done in $\binom{11}{1} \binom{21}{10} = 3\,879\,876$ ways.

- b** This identity can be established using the general solution of **a**, using n instead of 11. The number of choices is therefore $\binom{n}{1} \binom{2n-1}{n-1} \dots (1)$.

We can do this count in a different way.

Suppose we select i members from A and $n - i$ from B . There are i ways of choosing the captain from A .

So, we have $i \times \binom{n}{i} \binom{n}{n-i}$ selections where $i = 1, 2, 3, 4, \dots, n$

$$= i \binom{n}{i}^2 \quad \{\text{as } \binom{n}{i} = \binom{n}{n-i} \text{ by Pascal's rule}\}$$

Thus the total number of ways is $1 \binom{n}{1}^2 + 2 \binom{n}{2}^2 + 3 \binom{n}{3}^2 + \dots + n \binom{n}{n}^2 \dots (2)$

From (1) and (2), $1 \binom{n}{1}^2 + 2 \binom{n}{2}^2 + 3 \binom{n}{3}^2 + \dots + n \binom{n}{n}^2 = n \binom{2n-1}{n-1}$.

and the sign diagram of $\frac{dy}{dx}$ is:

$\therefore$ a local minimum occurs at $\left(-\frac{1}{2}, -\frac{1}{2e}\right)$

$$\therefore k = -\frac{1}{2e}$$

- b** The graph of $y = xe^{2x}$ is shown alongside.

- When $k = -\frac{1}{2e}$ or $k \geq 0$, $y = k$ cuts the curve once only.
- When $-\frac{1}{2e} < k < 0$, $y = k$ cuts the curve twice.
- When $k < -\frac{1}{2e}$, $y = k$ never cuts the graph.

c i When $y = xe^{ax}$, $\frac{dy}{dx} = e^{ax}(ax + 1)$

$$y = x \text{ meets } y = xe^{ax} \text{ where } x = xe^{ax}$$

$$\therefore x(1 - e^{ax}) = 0$$

$$\therefore x = 0, \quad a \in \mathbb{R}$$

When $x = 0$, $y = 0$ and $\frac{dy}{dx} = 1$, which is the gradient of $y = x$.

$\therefore y = x$ is a tangent to $y = xe^{ax}$, and the point of contact is $(0, 0)$.

ii The normal at $(0, 0)$ has slope -1 , and equation $y = -x$
 $\therefore$ it makes an angle of 45° to the x -axis.

$$P(A \cap B) = P(0B \text{ and } nG) = \left(\frac{1}{2}\right)^n$$

A and B are independent when

$$\therefore \left(\frac{1}{2}\right)^n = \left(\frac{1}{2}\right)^n (n+1) \times 2 \left(\frac{1}{2}\right)^n$$

$$\therefore 1 = 2(n+1) \left(\frac{1}{2}\right)^n$$

$$\therefore 2^n = 2(n+1)$$

$$\therefore 2^{n-1} = n+1$$

$$\therefore n = 3 \quad \{n > 1\}$$

$\therefore P_1$ is true.

So, with $n = 1$, $z + \frac{1}{z} = 2 \cos \theta$

$$\therefore \left(z + \frac{1}{z}\right)^3 = 8 \cos^3 \theta$$

$$\therefore z^3 + 3z + \frac{3}{z} + \frac{1}{z^3} = 8 \cos^3 \theta$$

$$\begin{aligned} \therefore \cos^3 \theta &= \frac{1}{8} \left[z^3 + \frac{1}{z^3} + 3 \left(z + \frac{1}{z} \right) \right] \\ &= \frac{1}{8} [2 \cos 3\theta + 6 \cos \theta] \\ &= \frac{3}{4} \cos \theta + \frac{1}{4} \cos 3\theta \end{aligned}$$

- b** Letting $x = \frac{1}{m} \cos \theta$, we have

$$\frac{\cos^3 \theta}{m^3} - \frac{3 \cos \theta}{m} + 1 = 0$$

$$\therefore \cos^3 \theta - 3m^2 \cos \theta + m^3 = 0$$

$$\therefore \frac{3}{4} \cos \theta + \frac{1}{4} \cos 3\theta - 3m^2 \cos \theta + m^3 = 0$$

$$\therefore \frac{1}{4} \cos 3\theta + \left(\frac{3}{4} - 3m^2\right) \cos \theta + m^3 = 0$$

which when choosing $m = \frac{1}{2}$ becomes

$$\frac{1}{4} \cos 3\theta = -\frac{1}{8}$$

$$\therefore \cos 3\theta = -\frac{1}{2}$$

$$\therefore 3\theta = \frac{2\pi}{3} + k2\pi \text{ or } \frac{4\pi}{3} + k2\pi$$

$$\therefore \theta = \frac{2\pi}{9} + \frac{k6\pi}{9} \text{ or } \frac{4\pi}{9} + \frac{k6\pi}{9}$$

$$\text{Now } x = \frac{\cos \theta}{\frac{1}{2}} = 2 \cos \theta$$

- 82 a**

As $\widehat{OPQ} = \theta$, $\widehat{PON} = 90^\circ - \theta$ and so $\widehat{NOQ} = \theta$

So, $\cos \theta = \frac{X}{d}$ and $\sin \theta = \frac{Y}{d}$

$\therefore X = d \cos \theta$ and $Y = d \sin \theta$

But $\sin \theta = \frac{d}{b}$ and $\cos \theta = \frac{b}{3}$

$$\begin{aligned} \therefore d &= b \sin \theta \\ &= (3 \cos \theta) \sin \theta \end{aligned}$$

Thus $X = 3 \sin \theta \cos^2 \theta$ and $Y = 3 \sin^2 \theta \cos \theta$

$\therefore N$ is at $(3 \sin \theta \cos^2 \theta, 3 \sin^2 \theta \cos \theta)$.

- iii Istvan will be between Paul and Laszlo in $\frac{1}{3}$ of all possible cases, since each of them will be the ‘middle student’ $\frac{1}{3}$ of the time.
 $\therefore$ the total number of ways $= \frac{1}{3}$ of $12! = 159\,667\,200$ ways.

- iv The students can be arranged in the form
- $$\begin{array}{l} A \times \times \times H \times \times \times \times \times \times \text{ in } 10! \text{ ways} \\ H \times \times \times A \times \times \times \times \times \times \text{ in } 10! \text{ ways} \\ \times A \times \times \times H \times \times \times \times \times \times \text{ in } 10! \text{ ways} \\ \vdots \\ \times \times \times \times \times \times \times H \times \times \times A \text{ in } 10! \text{ ways} \end{array}$$

- c i There are $\binom{12}{4}$ ways to choose the first group, $\binom{8}{4}$ ways to choose the second group, and $\binom{4}{4}$ ways to choose the third group. The order of groups is not important, so we divide by $3!$.
 So, there are $\frac{1}{3!} \binom{12}{4} \binom{8}{4} \binom{4}{4} = 5775$ ways.
- ii There are $\binom{2}{2} \binom{10}{2}$ ways to choose the group with Ben and Marton. There are then $\binom{8}{4}$ ways to choose the second group, and $\binom{4}{4}$ ways to choose the third group. The order of groups 2 and 3 is not important, so we divide by $2!$.
 So, there are $\frac{1}{2!} \binom{2}{2} \binom{10}{2} \binom{8}{4} \binom{4}{4} = 1575$ ways.

- 96** P_n is: “ $n^2 \times 1 + (n - 1)^2 \times 2 + (n - 2)^2 \times 3 + \dots + 2^2 \times (n - 1) + 1^2 \times n = \frac{n(n + 1)^2(n + 2)}{12}$,”
 for $n \in \mathbb{Z}^+$

Proof: (By the principle of mathematical induction)

- (1) If $n = 1$, LHS $= 1^2 \times 1 = 1$ and RHS $= \frac{1 \times 2^2 \times 3}{12} = 1$ Thus P_1 is true.

(2) If P_k is assumed true then

$$k^2 \times 1 + (k-1)^2 \times 2 + (k-2)^2 \times 3 + \dots + 2^2 \times (k-1) + 1^2 \times k = \frac{k(k+1)^2(k+2)}{12}$$

Thus,

$$\begin{aligned} & (k+1)^2 \times 1 + k^2 \times 2 + (k-1)^2 \times 3 + \dots + 3^2(k-1) + 2^2 \times k + 1^2 \times (k+1) \\ = & k^2 \times 1 + (k-1)^2 \times 2 + (k-2)^2 \times 3 + \dots + 3^2(k-2) + 2^2 \times (k-1) + 1^2 \times k \\ & + (k+1)^2 + k^2 + (k-1)^2 + (k-2)^2 + \dots + 3^2 + 2^2 + 1^2 \\ = & \frac{k(k+1)^2(k+2)}{12} + 1^2 + 2^2 + 3^2 + 4^2 + \dots + k^2 + (k+1)^2 \\ = & \frac{k(k+1)^2(k+2)}{12} + \frac{(k+1)(k+2)(2k+3)}{6} \\ & \{1^2 + 2^2 + 3^2 + 4^2 + \dots + n^2 = \frac{n(n+1)(2n+1)}{6}, n \in \mathbb{Z}^+\} \\ = & \frac{(k+1)(k+2)[k(k+1) + 2(2k+3)]}{12} \\ = & \frac{(k+1)(k+2)(k^2 + 5k + 6)}{12} \\ = & \frac{(k+1)(k+2)(k+2)(k+3)}{12} \\ = & \frac{(k+1)([k+1] + 1)^2([k+1] + 2)}{12} \end{aligned}$$

Thus P_{k+1} is true whenever P_k is true

$\therefore$ since P_1 is true, P_n is true for all $n \in \mathbb{Z}^+$. {Principle of mathematical induction}

$$V = \frac{4}{3}\pi r^3$$

$$\therefore \frac{dV}{dt} = 4\pi r^2 \left(-\frac{8}{5}\right) = -6.4\pi r^2$$

$$\text{At time } t = 2.5, \quad r = 8 - \frac{8}{5} \times 2.5 = 4 \text{ cm}$$

$$\begin{aligned} \therefore \frac{dV}{dt} &= -6.4\pi \times 4^2 \\ &\approx -322 \end{aligned}$$

$$\therefore A(2A-3)(A-2) = 21$$

$$\therefore 2A^3 - 7A^2 + 6A - 21 = 0$$

$$\therefore A = \frac{7}{2}, \text{ the only real solution } \{\text{technology}\}$$

e **i** $f_1(x) = 2 + 5e^{\frac{-2}{x^2+0.5}}$ has inverse function $x = 2 + 5e^{\frac{-2}{y^2+0.5}}$

From **b i**, the rearrangement making y the subject is $y = \sqrt{\frac{-2}{\ln\left(\frac{x-2}{5}\right) - 0.5}}$

$$\therefore g_1(x) = \sqrt{\frac{-2}{\ln\left(\frac{x-2}{5}\right) - 0.5}}$$

ii For $f_1(x) = 2 + 5e^{\frac{-2}{x^2+0.5}}$, as $x \rightarrow \infty$, $e^{\frac{-2}{x^2+0.5}} \rightarrow e^0$

$$\therefore f_1(x) \rightarrow 7$$
$$\therefore x < 7$$

As $f_1(x)$ is increasing for all $x \geq 0$, $\min_x = f_1(0) = 2 + 5e^{-4}$

$\therefore$ the range of $f_1(x)$ is $\{y \mid 2 + 5e^{-4} \leq y < 7\}$.

$\therefore$ the domain of $g_1(x)$ is $\{x \mid 2 + 5e^{-4} \leq x < 7\}$.
